connectedness with others.” Spirituality relates to values and beliefs that help a person to understand one’s life and gives it a direction (Westgate 1996; Fry 2003). Spirituality may be regarded as the guiding philosophy of our inner consciousness (Guillory 2000); it may be defined as “a process of self-enlightenment” (Barnett et al. 2000), “a worldview plus a path” (Cavanagh and Bandsuch 2002), “access to the sacred force that impels life” (Nash and McLennan 2001), and “the unique inner search for the fullest personal development through participation into transcendent mystery” (Delbecq 1999). Spirituality exists outside the realm of religion (Zullig et al. 2006). Spirituality has also been explained as inner experiences (e.g., Dillard 1982) and an attitude of openness, care, or loving which can be practiced and developed (e.g., Miller 2004; Wilber 2006). Spirituality refers to any kind of expression of interconnectedness, and therefore it is more inclusive in nature. Spirituality develops a sense of being at harmony with the world and a desire to serve others. Spiritual development is dynamic, and it involves (a) *awakening* of one’s self, others, and the universe, (b) *interconnecting* with others and the world, and (c) *believing it to be a way of living*. Through spirituality one may not be able to change the whole world, but one can change themselves.

Spirituality in Management

Management academics understand the spiritual perspective of work. Spirituality in management extends beyond traditional reflections on corporate purpose and focuses on a self-referential organizational-existential search for meaning, identity, and success. Quatro (2004) posits this point referring to the writings of Follett (1918) and Greenleaf (1970) in the classical management literature. Weber (1958) also called for developing management theories and practices de-emphasizing materialism and individualism. In more recent years, Nichols (1994) in Harvard Business Review raised the issue of spirituality by stressing on the fact that companies must find ways to “harness soul searching on the job, not

just gloss over or merely avoid it.” Humanistic (positive) psychology and integral psychology which emphasize on searching for such strengths that enable human goodness and resilience have received great attention in the recent years in the field of management academics (Fredrickson and Losada 2005).

The impact of spirituality on the business organization has been the matter of research globally. Studies have found that organizations managed by spiritual values (MBV’s) earned better returns within a period of 5 years. Organizations high on spiritual values outperform those without it on the parameters like growth, efficiency, and return on investment (Nur 2003). Fortune magazine in its analysis of “Best Places to Work” in the USA had stated that these are places where people find a purpose to work other than their pay checks (Colvin 2006). Meta-analysis by Dent et al. (2005) showed the positive association of spirituality with productivity. Spirituality positively affects work performance (Bromet et al. 1990; Jurkiewicz and Giacalone 2004). Marques et al. (2005) suggested that spirituality results in excellent output and community orientation. According to Jurkiewicz and Giacalone (2004), spirituality and performance are highly correlated which in turn results in motivation, commitment, and adaptability. Thus the field of management is ready to talk about spirituality (Zohar and Marshall 2000). Nurturing the “whole person” and developing “wholesome leadership” (Wakhlu 2000) are gaining increasing importance in the corporate world.

Key Issues and Future Directions

If we want to enhance the ethicality quotient in management decision-making, then the development of the “self” of the decision-makers is important so that they are in a more inclusive, holistic, and peaceful state of consciousness. This development of “self” is important because it helps a person transcend from self-conception to exercising genuine empathy with others and to take an all-compassing perspective. Today’s business practice is self-destructive and unsustainable.

Irreversible damages caused by science and technology-driven economic growth need to be stopped. Spirituality has to be the master. Spirituality has to be the benchmark for business projects. Business is fast destroying the ecological and cultural diversity, and the only way to prevent this is to practice spiritually based business because it can help business leaders to arrive at solutions which will serve the community and the planet and hence contribute to the enrichment of the world. In the context of spirituality, the purpose of management and business is not merely producing profit or increasing the market value of the company but also to serve the self-realization of all the persons involved including all the stakeholders. Efforts should be made to include spirituality as a subject in management education and then the young minds; minds of tomorrow's leaders shall know that their growth and development is not confined within a narrow space and their mindset is not curtailed and constrained to only financial parameters. Inclusion of spirituality in management education will help the leaders of tomorrow to make more responsible and moral decisions.

Description

In this entry, the concept of a stakeholder will be defined, some problems will be mentioned, and the application of the concept in business practice will be described, as well as uses and misuses of it. Before the 1960s, the word stakeholder had only gambling meaning; afterward, especially after 1984, it got additional business and business ethics meaning, and only a half a decade later, i.e., in 1991, some problems with it were diagnosed. A stakeholder in gambling “is an independent party with whom each of those who make a wager deposits the money, or is a person with an interest or concern in something,

especially a business” (Merriam-Webster Dictionary 2021).

The Development of the Stakeholder Concept

One of the basic concepts of corporate social responsibility (CSR), that is, the concept of a stakeholder, was introduced by R. Edward Freeman (Freeman 1984), although it is in use from the mid-1960s of the twentieth century. “A stakeholder in an organization is (by definition) any group or individual who can affect or is affected by the achievement of the organization’s objectives” (Freeman 1984). More to that, stakeholder became one of the central concepts surrounding business ethics, CSR, and sustainability. One of the basic problems with the concept of stakeholders, that is, the stakeholder paradox, was introduced by K. E. Goodpaster (1991). “It seems essential, yet in some ways illegitimate, to orient corporate decisions by ethical values that go beyond strategic stakeholder considerations to multi-fiduciary ones” (Goodpaster 1991, p. 63).

It makes sense that the manager has duties to more than just the shareholders. This seems a responsible thing to do. On the other hand, this as it seems requires the manager to break their fiduciary responsibility to the shareholders because they would sometimes have to put stakeholders’ interests above those of shareholders. Goodpaster suggests the solution to the paradox. In short, fiduciary duty should be reserved for shareholders, while CSR should be reserved for all other stakeholders.

A Remark on Literature Review

After the mid-1980s and the beginning of the 1990s, the criticism of the stakeholder theory went almost parallel with its application in business, nongovernmental organization (NGO), social theories, and even legislature.

R. E. Freeman, J. S. Harrison, A. C. Wicks, B. Parmar, and Simone de Colle in their *Stakeholder Theory, The State of the Art* supply the

history of the development of the theory, response to the criticism, but also quite important application of the theory to the sectors of finance, accounting, management, and marketing. Quite important issue, especially in the light of previously mentioned stakeholder paradox, is the relation of the stakeholder theory and capitalism (Freeman et al. 2010).

The overall account of the stakeholder theory is given in M. Bonnafous-Boucher’s and J. D. Rendtorff’s book *Stakeholder Theory, A Model for Strategic Management*. They supply not only the development and full expose of the theory but also criticism, development, application, and the relation to ethics, morality, and theories of justice (Bonnafous-Boucher and Rendtorff 2016).

One of the newest and perchance the most comprehensive overviews of the theory is *The Cambridge Handbook of Stakeholder Theory* edited by J. S. Harrison, J. B. Barney, R. E. Freeman, and R.A. Phillips. It covers theoretical foundations (1st part), stakeholder theory and society (2nd part), stakeholder theory in business disciplines (3rd part), stakeholder theory in education and practice (4th part), and new voices in stakeholder theory (5th part) which cover new theories in business administration and sciences. Behavioral approach is especially overviewed (Harrison et al. 2019).

M. Bonnafous-Boucher and Y. Pesqueux edited important collection of essays *Stakeholder Theory, A European Perspective* that cover many aspects of application of the theory in the European contexts (Bonnafous-Boucher and Pesqueux 2005).

A Note on Central Issues in Stakeholder Theory and Application

All issues concerning stakeholders and stakeholder theory and application can be divided according to various criteria, the most obvious of which are the following: issues in theory, issues in application, internal issues, and external issues. These can be combined in the division such as internal issues related to the theory and external issues related to the application.

Internal issues and relations to theories have various more or less interesting topics. A stakeholder paradox is an example of such issue. Issues concerning description, division, listing, order of relevance, intension, and extension of the term seem to fall under this group of issues.

The description of a stakeholder is quite important. Concerning the starting description suggested here, in the element in which it includes “person,” allows further difference between physical and legal persons, but it doesn’t allow informal social groups as a stakeholder. However, these are important if one wants to include ad hoc groups under the phenomenon of stakeholder activism. By analogy with the concept of corporate social irresponsibility (CSI) (Krkač 2019), the concept of anti-stakeholder can be formed. Given that CSI is extremely useful concept in analysis of business environments in which there seems to be a dominant lack of social responsibility, it seems that the cause of such actions can be traced among active or proactive anti-stakeholder, i.e., basically physical or legal persons (with states included), or even ad hoc groups that intentionally and premeditatedly refuse to identify themselves as stakeholders and systematically omit their stakeholder obligations.

Division of the term is also important, because it must explicate all possible stakeholders. This relates to the issue of listing stakeholders, possible or actual concerning a business sector, or an actual case. This also relates to making order of relevance among all possible or actual stakeholders which is important in formulating moral dilemmas and solving them. Without full division, list, and order of relevance of stakeholders, moral dilemmas can be wrongly formulated or even fictional without any relation to real situations. Stakeholder mapping therefore seems to be utterly important procedure. A quite frequent model of mapping of stakeholders, i.e., primary and secondary or social and nonsocial and similar, seems to be practically quite useful and prove itself as such in a series of practical cases.

External issues and relations to practice also have various more or less interesting topics. Some of these are the following: stakeholders and business ethics, stakeholders and CSR, stakeholders

and sustainability, stakeholders and general ethical theory, stakeholders and social ethics, stakeholders and individual or personal ethics, stakeholders and theories of justice, stakeholders and economic and legal constraints, stakeholders and politics, stakeholders and cultures, etc.

Concerning external issues, these concepts, i.e., business ethics, CSR, and sustainability, can be used interchangeably or as different parts or aspects of more general phenomenon of corporate or organizational morality. The first horn of the dilemma seems to be justified by the simple use of these concepts in business and ethical literature over the twentieth and twenty-first centuries, and the second horn of the dilemma can be justified by simple differentiation in their use, meaning that business ethics is used first and foremost in ethical codes, CSR is used primarily in decision-making process or model (meaning reaching, implementing, and measuring balanced, just, profitable, and legal business decisions), and sustainability is used primarily in dealing with primary nonsocial stakeholders (living and nonliving environment).

Most of the issues concerned with internal and external issues of stakeholder are dealt with in other entries in the present publication, so for any further analysis, it is quite important to search the cross-references.

Summary

The concept of a stakeholder is one of the most important concepts of contemporary organizational and corporate morality which seems justified by the fact that the vast majority of textbooks, dictionaries, companions, and handbooks in this field not only recognize the concept, the phenomenon, and its application in practice as utterly important but also discuss it in detail in their major parts.

However, from the beginning of the theory, and its application in business, legislature, and international documents and decisions, some problems seem to remain unsolved, starting with the known stakeholder paradox and continuing with some alternative theories. Yet, the theory proved itself by the success of its application in

practice, namely, by the measurable rise in responsibility if stakeholders are taken seriously.

[Stakeholder involvement](#)

Definition

Stakeholder engagement (SE) is the process used by an organization to engage relevant stakeholders for a clear purpose to achieve agreed outcomes. It is now also recognized as a fundamental accountability mechanism, since it obliges an organization to involve stakeholders in identifying, understanding, and responding to sustainability issues and concerns, and to report, explain, and

answer to stakeholders for decisions, actions, and performance.

This activity of systematic involvement by a company of its stakeholders on issues that have the requirement of materiality or relevance is a strategic element in business management as it aims to improve the quality of relationships with stakeholders and to achieve the greatest alignment of the products/services offered with the real needs of customers. Listening to stakeholders, speaking with them, and paying attention to their perceptions and expectations in the management of enterprises are, in fact, essential tools to better define the operations of the business, to align them with the demands of stakeholders, to improve the quality of the products and services provided also for internal stakeholders (direct effect), and to build and maintain a solid reputation in the market (indirect effect).

Introduction

The theoretical framework of the phenomenon of SE can be found in the literature on CSR and corporate governance, in particular in those studies concerning the form of dialogue and discussion among the main players in corporate life, the control bodies, or other internal and external parties of the company.

The stakeholders, being among the main protagonists of corporate life, feel the need to be integrated and contribute to improving the company in which they are involved. Therefore, SE becomes a composite process that includes more methods of interaction consultation, communication, exchange, and dialogue between the company and its stakeholders. Greenwood (2007) identifies SE as the set of procedures that an organization develops to involve stakeholders in organizational activity, in order to create a system of cooperation (Phillips 1997).

Stakeholder theory scholars have tried to classify the relational models between organizations and stakeholders by assuming a gradual growth of stakeholder involvement and participation. First, the organization identifies and maps its stakeholders, if possible distinguishing between primary parties (those who are strategic in the

middle to long term) and secondary parties (stakeholders that do not affect its sustainability) (Clarkson 1995). Second, it tries to manage stakeholders' expectations and the claims they support in accordance with their salience (Mitchell et al. 1997), while also balancing these various positions through a process of stakeholder management (O'Dwyer 2005). In the last step, organizations try to engage primary stakeholders in decision-making processes, making them participants in organization management and governance, sharing information, dialoguing, and creating a model of mutual responsibility. The stakeholder engagement phase, unlike the stakeholder mapping and management phase, "creates a dynamic context of interaction, mutual respect, dialogue and change, not a unilateral management of stakeholders" (Andriof et al. 2002). As a result, the main feature of stakeholder engagement is not to encourage the mere involvement of stakeholders to "mitigate" or manage their expectations, but to create a network of mutual responsibility.

Stakeholder engagement is a milestone corporate social responsibility (CSR) policy because it allows one party (the organization) to interact with another (the stakeholder) in a two-way dialogue in which the engager and engaged mutually learn from such contacts, deeply revising their expectations and preconceptions. In this sense, stakeholder engagement is a powerful tool of dialogic communication and accounting that offers interactive mutual learning processes that are capable of promoting transformative action and social change. According to Unerman and Bennett (2004), three key problems are associated with stakeholder engagement initiatives: identifying and reaching a wide range of stakeholders; determining a consensus set of stakeholder expectations from a range of potentially mutually exclusive views held by different stakeholders; and engaging them in an authentic two-way conversation. This does not exclude the possibility for stakeholders to communicate with each other without the intermediation of corporations that hold "legitimate interests" (Evan and Freeman 1988; Friedman and Miles 2006).

Furthermore, CSR engagement allows companies to reduce firm risk, and engaging in various

strategic and socially responsible CSR programs enhances corporate image.

SE has multiple values: it is a CSR instrument and a tool of good governance. It is also considered to be a key element in the preparation of sustainability reports; indeed, the standard GRI-G4 (international reference standards for sustainability reporting) attributes to SE crucial importance in defining the relevant information to be disclosed. In particular, according to the GRI-G4 guidelines, a company must identify its stakeholders and explain how it has responded to their reasonable expectations and interests.

Key Issues

The Institute of Social and Ethical Accountability has developed a process standard that provides a detailed explanation of the SE process and a set of practice guidelines to implement the standard **AA1000**. This standard is based on three principles:

- *Inclusivity*, which requires a timely process of dialogue and participation that facilitates broad involvement and balanced and determined results in strategies, plans, actions, and effects that respond to issues and impacts in an accountable way. According to this principle, a company should seek to better understand who its stakeholders are, what expectations they have, and how it can engage them.
- *Materiality*, which refers to the relevance of an issue to an organization and its stakeholders. A material issue affects the decisions, actions, and performance of an organization and/or its stakeholders.
- *Responsiveness*, which is an organization's response to stakeholder issues through decisions, actions and results, as well as communication with stakeholders. These can include establishing policies, objectives, and achievements; governance structures, processes, and systems; action plans; and SE methods, measurement, and performance monitoring.

In addition to these principles fundamental to an effective SE process, the **AA1000SES**

(AA1000 Stakeholder Engagement Process), most recently published in 2015, identifies four stages of this process: planning, preparation, implementation, and, finally, activation (as well as review and improvement) of engagement. The actions to be taken in each phase are identified.

The Global Reporting Initiative (**GRI-G4**), the international standard for sustainability, most recently published in 2013, also gives fundamental importance to the SE process. An essential principle of sustainability reporting is materiality, or the selection of topics considered to be relevant for reporting purposes not only to the company but especially to stakeholders. In this context, the choice of topics is considered to be material and consequently reported results from participatory dialogue with stakeholders. GRI-G4 provides guidance for the identification, selection, and prioritization of stakeholders and the activities undertaken in relation to the demands and emerging interests thereof. The standard introduces the principle of inclusivity and accordingly emphasizes the importance of the selection of proper stakeholders who are influential (able to influence corporate decision making), strategic (represent key stakeholders in corporate strategic choices), and close (have established, long-standing relationships with the company). The same principle calls for collecting stakeholders' instances and timely feedback. For this, the standard introduces the principle of comprehensiveness, particularly coverage of the material aspects essential to allow stakeholders to analyze the level of the company's economic, social, and environmental performance.

Finally, it should be noted that the framework on integrated reporting developed by the **IIRC** provides a review of the guiding principles for the preparation of integrated reports, assigning great importance to the SE process. The guiding principles are future-oriented strategic focus, connectivity information, stakeholder relationships, materiality, conciseness, reliability, completeness, consistency, and comparability. In stakeholder relations, the framework focuses on the level of attention that an organization must give to stakeholders' legitimate expectations and interests by regulating their necessary involvement in the materiality process.

Future Directions

The importance of the SE engagement is growing as more and more, as a strategic tool for the companies. The level of engagement may also change over time as relationships deepen and mature.

The method of engagement should be selected to best meet the needs, capacity, and expectations of the relevant stakeholders. More than one method may be selected for any given engagement. Different methods may be used concurrently or sequentially.

Consideration needs to be given to the relative merits of collective and individual consultation within stakeholder groups. For some groups, such as workers, providing views in a collective forum independent of management (such as through their union) is an essential part of providing anonymity for individuals and enhancing their capacity for influence.

As a consequence of this growing importance of SE, this process should be communicated. Communicating to stakeholders on the value and impact of engagement should go beyond providing feedback to stakeholders who participated in specific engagements. The organization should publicly report on the aggregate of its engagement activities together with overall outcomes and impact, to show the scope and breadth of its outreach, and to demonstrate how its engagements contribute value to its strategy and operations. Organizations should integrate reporting on stakeholder engagement with appropriate other forms of public organizational reporting (e.g., sustainability-related reports, annual or financial reports, website reporting, social media reporting).

Reporting on stakeholder engagement may include:

- Stakeholder groups engaged
- Approach to stakeholder engagement and methods used
- Frequency of engagement
- Primary issues and concerns raised through engagement

- Organization response to the engagement outcomes

Definition

Stakeholder governance is a concept that refers to the processes and systems used to manage the relationships and interactions between different groups and individuals who have an interest or stake in a particular project or organization (Frynas and Mellahi 2009; Raddick et al. 2009). Citizen science is a form of collaborative research that engages members of the public in scientific activities, such as data collection and analysis (Bonney et al. 2014a). The intersection of these two concepts, stakeholder governance and citizen science, is crucial for ensuring that community members are effectively engaged and that the goals of the project align with the needs and interests of all stakeholders.

Introduction

Citizen science is an approach that engages the public in scientific research, providing an

opportunity for individuals to contribute to scientific knowledge and decision-making (Stroud and Dickinson 2018). It is a growing field that is increasingly being used to collect data on a wide range of topics, from biodiversity to air quality. Citizen science has been predominantly pursued within the domains of the natural sciences (Crain et al. 2014; Goldin et al. 2021; Raddick et al., 2009). Activities and projects following social sciences and humanities topics and approaches are less easily discernible. One important aspect of citizen science is stakeholder governance, which refers to the ways in which different stakeholders, including researchers, community members, government officials, and industry representatives, are involved in the project design and decision-making process (Kullenberg and Kasperowski 2018). As the skew is toward the natural sciences, this “human” aspect is often inadequately addressed (Goldin et al. 2023). The British sociologist Alan Irwin in 1995) defined citizen science in the mid-1990s as both a science that assists the needs and concerns of citizens and a form of science developed and enacted by the citizens themselves. Irwin’s definition foregrounds the necessity of opening up science and science policy processes to the public (Balázs et al. 2021: p. 145 in Goldin et al. 2023; Irwin, 1995).

Effective stakeholder governance is critical for the success of citizen science projects, as it helps to ensure that the goals and priorities of the project align with the needs and interests of all stakeholders, particularly the community members. Stakeholder governance involves a proactive and collaborative approach that involves all stakeholders in the project design and decision-making process. This can lead to greater participation, trust, and understanding among stakeholders, and ultimately, more effective and sustainable outcomes (Bonney et al. 2014b; Goldin et al. 2023).

Recent scientific literature has emphasized the importance of stakeholder governance in citizen science. A study published in the *Journal of Environmental Management* (Kendall et al. 2018a) found that citizen science projects that involved community members in project design and decision-making were more likely to achieve their goals and have a greater impact on

conservation and management decisions. Another study published in the journal *Environmental Science & Policy* (Bonney et al. 2014a, b) found that effective communication between researchers and community members was critical for building trust and understanding, which in turn, led to greater participation and more successful outcomes.

In addition, a study published in the journal *Sustainability* (Wyborn et al. 2019) found that citizen science projects that involved a diverse range of stakeholders, including government officials and industry representatives, were more likely to have a greater impact on conservation and management decisions. The study also found that involving a diverse range of stakeholders helped to ensure that the project goals and priorities aligned with the needs and interests of all stakeholders. Goldin et al. (2023) emphasize that a concerted effort in engaging with stakeholders is conducive to building trust and that this will promote better stewardship of the environment. However, it is important to note that the engagement and involvement of different stakeholders, the level of trust, and communication channels will vary from one project to another and from one country to another (Haklay et al. 2021). Therefore, it is important to adapt the stakeholder governance approach to the specific context of each citizen science project.

Types of Stakeholder Governance in Citizen Science

Citizen science projects involve a wide range of stakeholders, including researchers, community members, government officials, and industry representatives (Silvertown 2009). These stakeholders have different goals and priorities, and the ways in which they are involved in the project design and decision-making process can vary. In this chapter, we will discuss the different types of stakeholder governance that are commonly used in citizen science projects.

One type of stakeholder governance is “top-down” governance, in which researchers and government officials are primarily responsible for the design and implementation of the project (Kendall

et al. 2018a). This type of governance is often used in projects that are focused on specific scientific or management goals, such as monitoring the impacts of climate change or managing a specific protected area. In top-down governance, community members may be involved in data collection, but they may have limited input into the project design or decision-making process.

Another type of stakeholder governance is “bottom-up” governance, in which community members are primarily responsible for the design and implementation of the project (Kendall et al. 2018a). This type of governance is often used in projects that are focused on community-based conservation or management, such as monitoring the impacts of logging or fishing on local ecosystems. In bottom-up governance, community members have a significant role in the project design and decision-making process, and researchers and government officials may be involved in a supportive or advisory role (Goldin et al. 2023; Haklay et al. 2021).

A third type of stakeholder governance is “co-governance” or “co-management,” which is a collaborative approach that involves community members, researchers, government officials, and other stakeholders in the project design and decision-making process (Wyborn et al. 2019). This type of governance is often used in projects that require a balance of scientific and local knowledge and perspectives, such as monitoring the impacts of climate change on local ecosystems or managing a specific protected area. In co-governance, all stakeholders are considered equal partners, and their input is valued and respected.

A fourth type of stakeholder governance is “crowd governance” which is a form of governance that is based on the collective intelligence of a large group of individuals, typically members of the public who are not experts in a specific field (Bonney et al. 2014a, b). This type of governance is often used in projects that rely on the collection of large amounts of data, such as monitoring air and water quality, or identifying species in large datasets. In crowd governance, the stakeholders are the public, and they are trained to collect the data needed, and the decision-making process is based on the data collected.

Each type of governance has its own advantages and disadvantages, and it is important for project managers and researchers to carefully consider the most appropriate approach for their specific project and context (Pocock et al. 2019; Goldin et al. 2022).

Challenges of Stakeholder Governance in Citizen Science

While stakeholder governance can be an effective approach for citizen science projects, it is not without its challenges. In this chapter, we will discuss some of the common challenges associated with stakeholder governance in citizen science.

One of the main challenges of stakeholder governance in citizen science is the lack of trust and understanding among stakeholders. This can occur when stakeholders have different goals and perspectives, and they may be unwilling to engage in open and honest communication (Bonney et al. 2014b; Goldin et al. 2023). For example, community members may be skeptical of researchers and government officials who they perceive as outsiders, while researchers and government officials may be hesitant to involve community members in the project design and decision-making process.

Another challenge of stakeholder governance in citizen science is the lack of participation among stakeholders. This can occur when stakeholders do not see the value or relevance of the project or when they have limited capacity to participate (Kendall et al. 2018b). For example, community members may be too busy with their daily activities to participate in the project, or they may not have the necessary skills or resources to participate.

A third challenge of stakeholder governance in citizen science is the lack of resources and expertise. This can occur when stakeholders do not have the necessary resources or expertise to participate in the project or when they are not provided with the necessary training or support (Wyborn et al. 2019). For example, community members may not have access to the necessary equipment or technology to collect data, or they

may not have the necessary training to participate in the project.

A fourth challenge of stakeholder governance in citizen science is the lack of cultural sensitivity. This can occur when stakeholders do not take into account the cultural, social, and political context of the project and when they do not consider the different expectations, norms, and values of stakeholders from different cultures, societies, and political systems. For example, community members from different cultures may have different expectations and norms regarding the involvement of women, the elderly, or children in the project, or they may have different expectations and norms regarding the sharing and use of data.

Best Practices for Stakeholder Governance in Citizen Science

Effective stakeholder governance in citizen science requires a proactive and collaborative approach that involves all stakeholders in the project design and decision-making process (Silvertown 2009). Effective stakeholder governance is critical for the success of citizen science projects, and there are several best practices that can be used to ensure effective stakeholder governance. In this chapter, we will discuss some of the best practices for stakeholder governance in citizen science.

One best practice for stakeholder governance in citizen science is effective communication among stakeholders. This involves creating open and honest channels of communication between researchers, community members, government officials, and industry representatives, to ensure that all stakeholders are informed and engaged in the project design and decision-making process (Bonney et al. 2014a,b). This can be achieved through regular meetings, workshops, and other forms of communication, such as newsletters, social media, and websites.

Another best practice for stakeholder governance in citizen science is involving stakeholders in the project design and decision-making process. This involves actively seeking the input and involvement of community members, government officials, and industry representatives in

the project design and decision-making process (Kendall et al. 2018a, b). This can be achieved through community consultations, focus groups, and other forms of engagement, such as survey and questionnaires.

A third best practice for stakeholder governance in citizen science is providing stakeholders with the necessary resources and expertise. This involves providing community members, government officials, and industry representatives with the necessary training, equipment, and technology to participate in the project, and ensuring that they have the necessary expertise and support to effectively participate in the project (Wyborn et al. 2019).

A fourth best practice for stakeholder governance in citizen science is being culturally sensitive. This involves considering the cultural, social, and political context of the project, and taking into account the different expectations, norms, and values of stakeholders from different cultures, societies, and political systems (Goldin et al. 2023; Haklay et al. 2021). For example, involving women, the elderly, and children in the project, and ensuring that the data collected is sensitive to the cultural, social, and political context of the project.

And finally, the fifth best practice is to reconsider tools when approaching stakeholders and opening up a more comprehensive toolkit that promotes stakeholder dialogue and encourages a more open engagement with science. Goldin et al. (2023) in their article “Keep the Flow” describe in more detail the way in which science and art collide and how the use of art-based tools can promote a better understanding of science. This includes using music, poetry, visual art, and graphic facilitation to convey science in a more “friendly” way to multiple stakeholders.

Role of Stakeholder Governance and Citizen Science in Sustainable Development and the SDG

Sustainable development and the United Nations’ Sustainable Development Goals (SDGs) are crucial global issues that require the participation and engagement of a diverse range of stakeholders

(United Nations 2021). The use of citizen science and stakeholder governance can play a significant role in achieving sustainable development and the SDGs by involving community members, researchers, government officials, and industry representatives in the collection, analysis, and use of data to inform decision-making (Bonney et al. 2014a, b). In this chapter, we will examine the role of stakeholder governance and citizen science in promoting sustainable development and the SDGs.

One way that stakeholder governance and citizen science can contribute to sustainable development is by involving community members in monitoring and managing local ecosystems. Community-based citizen science projects can help to ensure that the needs and perspectives of local communities are taken into account in conservation and management decisions, which can lead to more sustainable outcomes (Kendall et al. 2018b).

Another way that stakeholder governance and citizen science can contribute to sustainable development is by providing data and information to inform decision-making on a wide range of issues, including air and water quality, biodiversity, and climate change. Citizen science projects can collect large amounts of data on these issues, which can be used to inform policy and management decisions at the local, national, and global level (Bonney et al. 2014a, b).

A third way that stakeholder governance and citizen science can contribute to sustainable development is by building capacity and empowering communities to participate in decision-making and problem-solving. Citizen science projects can provide training and support to community members to help them participate in the project, which can build their capacity and empower them to participate in decision-making and problem-solving on a wide range of issues (Wyborn et al. 2019).

A fourth way that stakeholder governance and citizen science can contribute to sustainable development is by promoting inclusivity, equity, and diversity, which can help to ensure that the needs and perspectives of all stakeholders are considered in decision-making. This means involving a wide range of stakeholders. In the

project design and decision-making process, citizen science projects can promote inclusivity, equity, and diversity, which can help to ensure that the needs and perspectives of all stakeholders, including marginalized and underrepresented groups, are taken into account in decision-making (Curtin et al. 2020a).

In addition to these specific ways that stakeholder governance and citizen science can contribute to sustainable development, it is important to note that the SDGs are interconnected and mutually reinforcing, and citizen science projects can contribute to multiple SDGs. For example, a citizen science project aimed at monitoring and managing a protected area may contribute to SDG 14 (Life Below Water), SDG 15 (Life on Land), and SDG 11 (Sustainable Cities and Communities) by collecting data on marine and terrestrial biodiversity and promoting sustainable management of protected areas in local communities. In many instances, citizen science projects through promoting access to science and democratizing knowledge are also better able to address SDG 5 (Gender Equality), SDG 10 (Reduced Inequality), SDG 16 (Peace and Justice and Strong Institutions), and last but not least SDG 17 (Partnerships to Achieve the Goal).

Technological Trends and Futures of Stakeholder Governance and Citizen Science

Technology is rapidly advancing and has the potential to significantly impact stakeholder governance and citizen science. In this chapter, we will discuss some of the key technological trends that are shaping stakeholder governance and citizen science.

One key technological trend is the increasing use of mobile technologies in citizen science. Mobile technologies, such as smartphones and tablets, are becoming more widely available and affordable, and they are being used to collect and share data in citizen science projects. For example, the iNaturalist app, which allows users to take photos of plants and animals and share them with a community of experts for

identification, has been used in a number of citizen science projects (Bonney et al. 2014a, b).

For example, AI algorithms have been used to analyze data from citizen science projects aimed at monitoring bird populations, which can help to identify which species are most in need of conservation efforts. Besides, virtual reality can be used to simulate fieldwork in remote or difficult-to-access locations, while augmented reality can be used to overlay information on the natural environment, such as the location of endangered species.

Another key technological trend is the use of blockchain technology in citizen science. Blockchain technology can be used to securely store and share data collected in citizen science projects, which can help to ensure the integrity and privacy of the data (Curtin et al. 2020b). This can be especially important when sensitive or personal information is being collected, such as information on endangered species or human health.

The advancement of technology presents new opportunities for stakeholder governance in citizen science. Big data, IoT, drones, and virtual/augmented reality can enhance participation, data collection, and engagement. Recent studies have highlighted the potential of these technologies in citizen science, such as using big data to inform environmental decision-making (Bonney et al. 2019), IoT for monitoring biodiversity (Kendall et al. 2018b), drones for mapping and monitoring natural resources (Wyborn et al. 2020), and virtual/augmented reality for engaging and educating stakeholders (Curtin et al. 2020c). These technological trends demonstrate the potential for technology to enhance stakeholder governance and citizen science by increasing participation, improving data analysis, and providing immersive experiences that can increase the understanding of science.

Case Studies

Citizen science is a form of collaborative research that engages members of the public in scientific activities, such as data collection and analysis

(Bonney et al. 2014a, b). Citizen science projects involve a wide range of stakeholders, including researchers, community members, government officials, and industry representatives (Silvertown 2009). The ways in which these stakeholders are involved in the project design and decision-making process can vary depending on the specific goals and priorities of the project. In this chapter, we will discuss several case studies and examples of stakeholder engagement in citizen science.

One example of stakeholder engagement in citizen science is the “Citizen Science at Table Mountain National Park” project in Africa. This project, which is a collaboration between the University of Cape Town and the South African National Parks, uses the iNaturalist app to gather data on the distribution and abundance of plant and animal species in the Table Mountain National Park. The project has been successful in engaging a wide range of stakeholders, including local residents, tourists, and school groups, in data collection and conservation efforts. This is an example of bottom-up governance, where community members are primarily responsible for the design and implementation of the project, and researchers and government officials are involved in a supportive or advisory role (Rouget and Richardson 2019).

Another example of stakeholder engagement in citizen science is the “Virtual Amazon” project in South America. This project, which is led by the Brazilian Institute of Environment and Renewable Natural Resources (IBAMA), uses virtual and augmented reality to engage stakeholders in a citizen science project aimed at monitoring and managing protected areas in the Amazon rainforest. The project has been successful in providing immersive experiences for stakeholders, increasing understanding and engagement with the project goals and objectives (IBAMA 2019). This is also an example of co-governance or co-management, where community members, researchers, government officials, and other stakeholders are involved in the project design and decision-making process.

A further example of stakeholder engagement in citizen science is the “CrowdWater” project in

Europe. This project, which is a collaboration between several European research institutions, uses crowd governance to collect data on water quality and quantity across Europe. The project has been successful in engaging a large number of citizens in data collection and analysis, providing valuable information for water management and conservation efforts (Seibert et al. 2022). This is an example of crowd governance, where the stakeholders are the public, and the decision-making process is based on the data collected.

These case studies and examples demonstrate the various ways in which stakeholders can be engaged in citizen science projects, and the benefits that can be achieved through effective stakeholder engagement. The “Citizen Science at Table Mountain National Park” project and “Virtual Amazon” project are examples of bottom-up governance and co-governance or co-management, respectively, where community members are primarily responsible for the design and implementation of the project. The “ButterflyWatch” project and “CrowdWater” project are examples of co-governance or co-management and crowd governance, respectively, where community members, researchers, government officials,

Diamonds on the soles of their feet (DSF) is an ongoing project where citizen scientists have been involved in collecting data on groundwater in very remote rural wells in the Limpopo Province of South Africa. This has shown improved water literacy and better understanding of water resources management. It has also provided a space for youth ambassadors to link with the Adopt a River, Department of Water and Sanitation Programme, thus bridging the gap between the public and government and promoting better stewardship of rivers through very simple technology (MiniSass and the UN Freshwater Quality Kits).

Summary

In summary, the paper delves into the importance of stakeholder governance in citizen science projects, highlighting the benefits and key concepts associated with it. The paper also discusses

different types of stakeholder governance and citizen science, as well as the challenges and best practices associated with it. Additionally, the paper provides case studies and examples of citizen science projects from different parts of the world, highlighting the role of stakeholder governance in sustainable development and the SDGs. Furthermore, the paper discusses the technological trends in stakeholder governance and citizen science, including the use of mobile technologies, machine learning and AI, virtual and augmented reality, and blockchain technology, and also provides recommendations for improving stakeholder governance and citizen science in the Global South and its impact on development. Overall, the paper emphasizes the importance of community engagement and participation, inclusivity and equity, training and capacity building, and the appropriate use of technology in stakeholder governance and citizen science.

Stakeholder Management

Markus Becker¹ and David Bendig ²

Description

Stakeholder management describes a systematic approach of interacting with individuals, groups and organizations who have an interest in an organization. The parties influenced by an organization's activities are called stakeholders. In the case of business companies, typical stakeholder groups include customers, suppliers, employees, financiers, as well as a local and global community. The process of addressing these groups can be broken down into individual steps. Those range from an initial prioritization of stakeholders, to the realization of a differentiated strategy, up to the measurement of success and associated loops of feedback and learning. This entry yields an

overview of such basic stakeholder management activities and frameworks. Still, flexibility in the execution of these steps can help to tailor the solution to a given problem. Moreover, as stakeholder management conceptually aims at actively shaping exchange relationships in a way that integrates interests against the background of value creation, this entry presents a critical perspective on whether this is achieved in reality. In complementation of stakeholder theory, agency theory provides a foundation for this discussion. The entry closes by accentuating empirical findings on stakeholder management with regard to corporate social responsibility, a known field of conflicting interest, illustrating that stakeholder management should not turn into stakeholder manipulation.

Fundamentals of Stakeholder Management

According to ► [stakeholder theory](#), stakeholders are “groups of persons who have a stake, a claim, or an interest in the operations and decisions of the firm” (Cai et al. 2012: 469). Following this view, managers are expected to bring their own and their firms’ goals into balance with the expectations of those ► [stakeholders](#) (Donaldson and Preston 1995). In other words, stakeholder theory describes how managers act in the attempt to align stakeholder interests and their firm’s achievement of objectives efficiently (Freeman 1984). Accordingly, the activities of a business can be depicted as constellation of relationships with those stakeholders, directed towards ► [value creation](#) (Freeman 2017), and stakeholder management can be defined as management of these relationships (Freeman et al. 2007). While the approach can be applied to organizations and projects of various kinds, the emphasis in the following shall be on managing the stakeholders of a business company.

As illustrated by Miles (2017), an exhaustive, consensual taxonomy of stakeholders may be neither feasible nor aspired. Yet, to address and shape corresponding relationships in the sense of stakeholder management, classifications related to

business traditionally mention certain groups: financiers, employees, customers, suppliers, regulators, the local community, and the overall society. As criterion for categorizing those stakeholders can be seen which type of “stake” those hold in the business. Thus, to allow a targeted management of stakeholders, it is essential for a company to understand what creates value for each of these, simply put “what everyone wants.” Following Freeman (2017), different stakeholders’ interests are by no means independent of one another but can be interconnected to varying extents. As such, *financiers* have invested into a company, and therefore aspire to participate in its profitability by means of return. For *employees*, their company is crucial to make a living, as it provides salary and further forms of remuneration for the employees’ work contribution, as well as structure and meaning. *Customers*, as recipients of a company’s goods and services, are interested in a reliable satisfaction of their demands. Conversely, *suppliers* consider the focal company as part of their customer base, being vice versa interested in addressing its demands by means of market-directed activities. *Regulators* and their enforcement organizations desire that organizations adhere to their standards. The *local community*, in the understanding of stakeholder management, is affected by the physical presence of a company, which it allows and supports, receiving socio-economic benefit in exchange. This local perspective can be extended by considering *society at large*, referring to everyone affected by the company on a global level.

Some views are known to give most attention to the role of customers in stakeholder management, similar to traditional approaches of marketing (Friedman and Miles 2006). Yet, as argued by Freeman (2017), the scope of an employed stakeholder definition should be adapted to the present task a company seeks to fulfill. For example, if a decision affects one stakeholder group in particular, further segmentation within this group might be helpful. Broader categories might also apply for strategic decisions on a global scale. With stakeholder management aiming at addressing each stakeholder group in the best way against the background of a given problem, the adequacy

of groups defined is crucial for its success. Following the notion by March and Simon (1958) that relationships between a company and its stakeholders have the nature of an exchange, it becomes apparent that a flexible grouping of stakeholders might be required depending on the type of a given exchange, facilitating targeted actions as a result.

Stakeholder Prioritization and Management Process

To describe the activity of stakeholder management as a process, literature yields various approaches with different suggestions regarding number and types of steps involved. However, based on a literature review by Pedrini and Ferri (2018), three steps can be derived as an essence: (1) ► [strategy](#) development, (2) strategy execution, and (3) performance measurement. As the authors explain, *strategy development* involves the definition of targets, planning of target-directed activities, and provision of required resources. In the subsequent step of *strategy execution*, this strategy is to be implemented by means of the agreed procedure and resources. Subject of the final step, *performance measurement*, is the systematic comparison of achieved and planned outcomes.

While this process description is intentionally generic to reflect consensual patterns in literature, detailing and adding steps can contribute to tailoring the process to specific questions of stakeholder management. As such, the *identification* of stakeholder groups as described above can be seen as an initial step on its own, further complemented by a *prioritization* of those groups. Basic dimensions of prioritization are interest and power, often graphically depicted as two-dimensional grid as introduced by Mendelow (1991). While *interest* refers to how a stakeholder is affected by company activities and attaches importance to these, *power* refers to the extent of the influence on the company. Based on a stakeholder's position on this grid, managerial actions can be chosen accordingly. For instance, stakeholders which are both high in interest and power,

like key customers, could be managed more actively than such with low interest and low power. The latter, like distant members of the local community, would rather need monitoring to allow the company to get active when necessary. A related concept, allowing to prioritize conflicting demands from different stakeholders in particular, is *stakeholder salience*, involving the dimension of power as well, but with legitimacy and urgency in addition (Mitchell et al. 1997). For example, a configuration of stakeholders with high legitimacy and urgency, but with low power, is seen as challenging. This rests on the assumption that, in lack of power, these are more likely to pursue their interests by means of unlawful measures.

Another extension of the basic stakeholder management process promoted by scholars refers to linking its last step of performance measurement back to the beginning, portraying stakeholder management as an ongoing activity or cycle. With this understanding, companies exhibit a learning curve based on prior interactions, allowing them to adapt the development of their stakeholder strategy accordingly and exchange feedback with their stakeholders. Moreover, it shall be noted that this process of stakeholder management is certainly not to be seen stand-alone but related to further key activities as ► [stakeholder engagement](#) in the understanding of a dialogue (e.g., Unerman 2010).

Stakeholder Management as Agency Problem, by Example of Corporate Social Responsibility

According to ► [agency theory](#), stakeholders can be understood as principals, while the company, or more precisely its management, functions as their agent (Jensen and Meckling 1976). However, as outlined by Hill and Jones (1992), managers have information advantages over the company's stakeholders. By simply knowing more about the true actions of their company, based on first-hand insider knowledge, managers are able to pursue their own utility, deviating from the utility functions of respective stakeholders

(Jensen and Murphy 1990). Under ideal – yet hypothetical – conditions as perfect information and efficiently balanced incentives, managers would act in the stakeholders' interest alone (Freeman 1994), so their demand for ► [corporate social responsibility](#) (CSR) would be considered in an adequate manner and reported back to them in a transparent way (Reynolds and Yuthas 2008). Yet, with the actual situation being characterized by ► [moral hazard](#), managers are tempted to act opportunistically instead (Warfield et al. 1995). Further following agency theory, the deviance from stakeholder interests is explained by two models: hidden action, and hidden information (Grant et al. 1996).

Hidden action models describe that stakeholders can neither observe their agents' actions objectively, nor in a perfect manner (Narayanan 1985; Stein 1989). Thus, stakeholders have to assess managerial actions based on limited information, which they either receive from the company directly, or have no choice but gathering on their own with additional effort. By means of their proprietary information, managers and therefore companies can act in a way that not primarily follows, or even contradicts, stakeholder interests. With stakeholders defined as those affected by a company's actions, hidden action models make apparent that it is not necessarily clear to stakeholders what the company's actions even are. With respect to the activity of stakeholder management, this equips companies with degrees of freedom that constitute an asymmetry within the exchange relationship between company and stakeholders. *Hidden information models* explain that companies can act opportunistically even if their behavior can – at least partially – be observed by stakeholders. With a sense for which impression certain actions make on stakeholders, companies can steer these impressions by acting in a way that results in beneficial interpretations on the side of stakeholders. In other words, companies can not only obtain and use insider information, but also signal a message towards stakeholders which is favorable, but might be manipulative or false (Spence 1973). It is noteworthy that managers are technically also stakeholders of a company themselves; however, against the

background of a “stakeholder-agency theory,” they are understood as firm representatives that “filter or distort” the communication directed towards other stakeholders (Hill and Jones 1992: 140).

From an empirical point of view, a well-known example for the exploitation of managerial information advantages in the course of stakeholder management is the field of CSR, particularly its reporting. Henceforth, following the argumentation by Kroeckel et al. (2018), it is initially to be stated that the concept of CSR has a research tradition which is likewise long and divergent (cf. Carroll 1999). From a narrow perspective, any social responsibility of companies would be limited to profit maximization within the scope of action which is legally possible (van der Wiele et al. 2001). Allocating resources to non-profit applications, such as charity, would be unreasonable, as detrimental to this overarching target of profitability (e.g., Pinkston and Carroll 1996). A broader view on CSR describes it as activities “beyond the interests of the firm and that which is required by law” (McWilliams and Siegel, 2001: 117). Over time, four conceptual positions have been suggested based on the latter: (1) CSR as *social* obligation to anyone (Bowen 1953), (2) CSR as obligation towards *stakeholders* alone (Clarkson 1995), (3) CSR as *ethics-driven* without any self-interest of the company (Swanson 1995), and (4) CSR as a managerial *process* with a focus on being responsive to stakeholder demands (Ackerman 1975).

Against these viewpoints, the *reporting* of CSR can be condensed to “the process of communicating the social and environmental effects of organizations' economic actions to particular interest groups within society and to society at large” (Gray et al. 1996: 3). Simply put, ► [CSR reporting](#) means nothing else but communicating content about CSR – however, it is not guaranteed that the reported content is sincere. According to stakeholder theory, CSR reporting in the course of stakeholder management does not necessarily reflect the ethical principles that the concept of CSR itself leads to expect. Instead, CSR reporting can be a means to the end of expressing fulfillment of stakeholder requirements (Berman et al. 1999;

Ballou et al. 2006). Hence, CSR reporting is partially the attempt of companies to show themselves in a good light and satisfy stakeholders in the first place (Hooghiemstra 2000; Patten 2002). Albeit companies might act in alignment with actual stakeholder interests, it is to be concluded that CSR communication is genuinely a measure to fulfill stakeholders' demand for CSR information, not necessarily for CSR itself (McWilliams and Siegel 2001).

Consequently, the levels of CSR that companies proclaim are empirically identified as inaccurate reflections of their CSR level if assessed by ratings, or even intentionally misleading, as detailed in the following. First, the communication of CSR by companies focuses on positive CSR events, neglecting negative ones (Scalet and Kelly 2010). Second, companies systematically intensify their CSR communication in response to scandals (Arvidsson 2010; Gray et al. 2001). Third, CSR communication is employed to camouflage controversial business practices in the spirit of greenwashing (Laufer 2003; Delmas and Burbano 2011). Fourth, while the concept of CSR empirically exhibits a positive association with company performance, its reporting alone is known for the opposite relationship if it is revealed to be exaggerated (Barnea and Rubin 2010; Cai et al. 2012). And fifth, companies conducting socially irresponsible practices are more likely to even take preventive measures against future controversies by increasingly proclaiming CSR activity in the sense of an "insurance" (Kang et al. 2016). In the context of agency theory, these empirical findings about CSR communication suggest that companies exploit, and even expand, existing information advantages over their stakeholders. In the spirit of Akerlof (1970), the circumstance that company characteristics are neither fully visible nor credible for stakeholders is related to inefficiencies; in the case of CSR, stakeholders have difficulties to distinguish sincere from manipulative information, hindering their pursuit of legitimate claims related to the activities of a company. In the long term, successful company-stakeholder relationships are characterized by an open and honest communication (Rolloff 2008), corresponding to

the nature of these relationships as an exchange between interdependent parties in value creation – with value not being limited to financial value creation in the firm but also stakeholder value beyond financial and firm goals.

Stakeholder Mapping

Mapping of a company's stakeholders

Description

An expression “A picture is worth a thousand words” (Flanders 1911, the expression is in fact a paraphrase of Henrik Ibsen’s words: A thousand words leave not the same deep impression as does a single deed.) applies to most pictures, images, and perhaps symbols as well, and maps are no exceptions to the rule given the fact that a stakeholder mapping as modeling results with a stakeholder map as a model which as an image presents itself and as a guiding pattern imagines future actions.

A stakeholder mapping (further on abbreviated as SM) is a new name for an old practice and a technique that was performed from the beginnings of business practice, perhaps even from the beginning of a mankind. When performing actions that will influence many, humans are capable of seeing and planning the influence of their actions on all relevant parties in a way that they maximize the success of an action and minimize the harm of it on others. In early humans, these include primordial elementary practices of pattern recognition and modeling actions. When this is done in business, it is called SM (Mendelow 1991; Goodpaster 1998).

Since the introduction of the stakeholder concept by the “father of stakeholder theory” (Laplume et al. 2008) R. E. Freeman (Freeman 1984), the issue of how to identify, mutually relate, present, and apply stakeholders in a business, or how to do a stakeholder mapping, was raised and answered in business theory, business practice, and many overlapping spheres of human

activities (in science, culture, and everyday private life). A single reasonably justified, accepted by majority of experts and practitioners, and applied model of stakeholder mapping is not yet found. However, many models have proven themselves clear and consistent in a conceptual business modeling and are successfully applied in business practice.

The Nature and Risks of SM Modeling

In business administration and in its aspect of stakeholder management and corporate social responsibility (CSR) a SM is the modeling of stakeholders and their stakes in the perspective of their relevance (various criteria of relevance are listed here) for a particular business process and vice versa (synonyms include stakeholder analysis, stakeholder visualization, etc.). The first steps of stakeholder management include SM, i.e., stakeholder identification, stakeholder needs documentation, stakeholder interests, and expectations analysis (while management of these, reviews, and repeat of actions belong to further steps which depend on this conceptual modeling). SM can be done for any organization whatsoever and for any company, business period, business plan, brand, line of products or services, or even for a particular product or a service.

Concerning criticism of and response to SM, it does not exist really; rather it is a kind of continuity of more fundamental debates about stockholder vs. stakeholder theory of corporation (the so-called Friedman vs. Freeman Debate), fiduciary duties of company directors, and especially the stakeholder paradox (Goodpaster 1991) since, if among stakeholders, there are others than stockholders and which all have the same conceptual position or for that matter different, what does it mean for the concept of multiple stakeholders listing and mapping (Neville and Menguc 2006)? What exists here concerning criticism is a kind of competition between various SM modeling lists, criteria, divisions, visualizations, and applications in business practice. Many business people, practitioners, ethical officers, activists, researchers, and professors have their own way

of SM; sometimes they use the known ones with their slight “improvements,” and sometimes they invent completely new ways (but there is no much innovation on this matter).

Given that previously said is correct, in what follows the nature and risks of SM modeling will be described in terms of types of SM in view of stakeholder listing, mapping, and visualization, and some concluding remarks will be supplied concerning various SM modelings and risks of making most frequent mistakes in business practice.

SM concerns two major tasks. The first is an identification of relevant stakeholders (further on abbreviated as RS) and their mutual relations in view of a particular business process, and the second is an identification of relevant stakeholders’ interests (further on abbreviated as RI) in view of a particular business process. These two tasks are obviously different and should not be mixed due to unnecessary risks that the mixture can produce during the realization of a business plan, and on the other hand they are interdependent.

RS is obviously vital since it is important to identify all relevant stakeholders. Dangers are also obvious. Some of them include non-identification of a stakeholder, misidentification of a stakeholder, mixing stakeholders in different groups without clear reason or a criterion, etc. These dangers can influence results of a business process. For example, a fairly small and irrelevant stakeholder group can be non-identified, and it can produce high risk during the business process in which there will be no resources to deal with potential harm that this non-identification can probably produce.

RI is obviously vital as well since even if all stakeholders are properly identified, it is by all means possible to identify them under the wrong aspect.

More to that, since interests of stakeholders differ if viewed from the side of a business and from the side of a particular stakeholder group, it is important to meet these interest with minimal possible overlap. In principle, SM is a practice done by a company toward its stakeholder. However, it is often enlightening and wondrous to see a

duck as a rabbit or that two arrows are actually of the same length.

For example, a group of employees during an introduction of a new business practice can view their interest in higher payments due to more learning and work that they have to do regularly, and it can also be a fact that in overall time of a business process, they will be more efficient and actually work less with better results, so it is quite important to set straight the real RI and to present these RI to relevant stakeholders.

SM is quite often presented visually, i.e., in terms of an actual map which represents identified and mutually related stakeholders of a business. This is an excellent way to do it; however, at least two dangers can occur. The first is that this is only a half of a job of SM since stakeholders’ interests should be presented as well. The second is that such presentations are static, i.e., they present stakeholders as if they have one and the same relation, say hierarchical, toward the business process, while in reality their relations are different and often change due to goals and risks of a particular stage of the business process.

For example, innovators, inventors, or generally speaking research and development (further abbreviated as R&D) and market researchers are of utmost importance at the beginning of marketing process of a particular product, while in the middle of it when sale is important, or at the end of it when say recycling is important, completely different groups of stakeholders and interests may be more important since not taking them into account especially if it is possible to do so with cutting costs can present unnecessary risk of failure of the business process.

Therefore, SM besides visual presentation should also present their interests, and if possible their change if it is highly probable, and also the change of their relation to business during all stages of a business process (fortunately enough nowadays there are various computer software that can help professionals in such presentations and some of them are even open source).

It should not be forgotten that SM is first and foremost a practice, a technique, and a conceptual modeling procedure which explicates already present and manifested but implicit concepts, groups,

and interest in order to achieve minimal clarity and perspicuity needed for reasonable, just, and successful business practice (decision-making process and standard operating procedures; further abbreviated as SOP). As such, SM by being performed by professionals is an integral aspect not just of an overall business plan, but of overall process of a business practice, of a daily life of a company.

The results of SM include identification of stakeholder groups, identification of their interests, mutual interdependence of stakeholders and their interest, identification of the stakeholders' relevance for the success of the business practice in all its stages, potential risks (by negative stakeholders), etc. Without reaching these results, a business practice can be legal, potentially financially successful, and in the same time overall failure due to various misunderstandings and misidentifications of stakeholders and their roles in a business process (this issue goes under the topic of the corporate social irresponsibility (CSI) which is as important as CSR).

Types of SM Modeling I: Listing

In order to model stakeholders and their interests, one has to have some criteria. These criteria vary from simple non-business to quite precise business variable, the former often including more universal variables such as primary/secondary, social/non-social, and key/lesser, while the later including more particular business features such as potential for cooperation (Savage et al. 1991), power, legitimacy, support (Mitchell et al. 1997), satisfaction (Turner et al. 2002), value hierarchies and key performance areas (Fletcher et al. 2003), and need and importance (Cameron et al. 2010).

Criteria of modeling SM are irrelevant as far as they cover all relevant stakeholders, namely, owners, management, employees, suppliers, buyers, customers, competitors, markets, state, media, NGOs, environment, eco- and bio-systems, etc. It is quite important to understand that these criteria do not differ between stakeholders strictly but only in level, since mapping is a practice and technique and as such it does not

need strict distinctions and concept borders (blurred are enough), rather the adjustment capability.

Differing between primary and secondary, and/or key/other stakeholders, is quite useful criteria since these standards split them by importance (internal value, need, interest, expectation, etc.) which should be viewed in scope of a business plan. These basic criteria are often combined with others among which social/non-social criterion is also practically useful since social stakeholders include present groups of humans which are managed directly, while non-social include besides past and/or future groups of humans also non-living environment, ecological and biological systems, or surroundings which can be managed only indirectly, that is to say via some social group (professionals in a company, governmental organizations, NGOs, or similar).

By using such quite tolerant and simple criteria and by adding some special due to special features of a business plan, and if the same is done with their basic interests and risks as stakeholders of a business plan, one gets a stakeholder list. Such list in majority of cases include standard stakeholders such as the following (here they will be grouped in accordance with mentioned criteria): stockholders and management (all levels); employees and suppliers (primary-social-key), further on market, media, key competitors, local communities, governmental and NGO organizations, and similar (secondary-social-other) in which buyers, users, and customers are exception in case of lifelong customers (which can be treated as primary); also resources, various levels of environment, and similar (primary-non-social-other here, but key from the sustainability perspective); and finally all organizations which care for all primary-non-social-other stakeholders (therefore, secondary-non-social-other).

Types of SM Modeling II: Mapping and Visualizing

However, a list is not a map. In order to create a stakeholder map, one needs to put stakeholders from the list in relation to the business plan and to

each other. These relations can differ in time, strength, nature, and similar (see Wolfe and Putler 2002 for various issues concerning stakeholder relations). If a stakeholder list is combined with one or more criteria, one gets a stakeholder map, as it was shown in previous paragraph in which list of stakeholders was combined with already mentioned universal criteria: being social/non-social, primary/secondary, and key/other.

Relations between stakeholder groups should always be justified by a strict application of one or more clear criteria. No matter what a system of relations actually is, various systems can be graphically presented in the same way, and one system can be presented in different ways. For example, a three-criterion system of features, social/non-social, primary/secondary, and key/other, can be visually presented in a circular, hierarchical, or grid model. Only when such systems are visually presented, they are in fact mapped and are a stakeholder map. This is so because a map is not just a visualization of system of formal relations between concepts and/or of a system of morphological relations which will determine future actions but previous to that and perhaps more importantly, a conceptual pattern, model, and as such a guide of future business actions.

Therefore, it is quite important that a system of relations between stakeholders from the list is visually presented in a way that on the one hand, it corresponds to the system and that on the other hand, it corresponds to the future business actions and the whole business process. It is also important that the final map is consistent and if possible coherent with the overall business plan, i.e., its all aspects.

Such finished stakeholder maps naturally forms various graphical forms, such as hierarchical form (pyramids or reversed pyramids), circular form (diagrams), parallel diagrams, overlapping (Venn's) diagrams, matrix, various grids (two-, three-, or multidimensional grids), three-dimensional grouping, and sometimes even grouping which vary in time periods of business activity. As said, it is of utmost importance that visual/graphical presentation of a stakeholder map fits the features of a general stakeholder

management plan which should fit the overall business plan. It is easy that a stakeholder map by its visualization, for instance, by hierarchical form, should suggest strict, fast, and precise execution, while in reality the system of relations between stakeholders suggest execution with parallel constant dialogues and accommodations, say due to the nature of a new and revolutionary product or a service (for various shortcomings of such visualizations, see Fassin 2008).

However, some manners of graphical presentations of SM are more frequent than others. If one conducts simple online test by checking various Internet search engines for stakeholder mapping, analysis, and visualization (as the present author did in 2017 concerning images and repeated in 2021), the results would be the following. Out of first 100 images (their sources were checked in order to verify that the image concerns the stakeholder mapping) on 3 search engines approximately ($\pm 2\%$), 37% were two-dimensional grids with 2 criteria, 28% were mutually connected stakeholders with arrows (in squares, balloons, and similar shapes), 23% were presented via overlapped Venn's diagrams, and 12% were presented in parallel circles with the same center and different radiuses or pyramids with layers (the research was done as a part of business ethics, CSR, and sustainability MBA course at ZSEM).

Concerning color, a vast majority (94%) use various colors consistent with rules of use in terms of basic visual literacy, and only minority (6%) do not use color but supply visualization in black and white. The ratio of text, color, shapes, and various connectors in almost all cases is normal and enables clear view, but not always a clear understanding. Other features are mostly simple and are given by default, because of possibilities of computer software (it should be mentioned that there is some percent of stakeholder maps that are drawn by hand during presentations and this should not be underestimated because drawing a map, especially by an experienced and talented draftsman, is a process followed by additional experience of flow or procedural nature of SM which is often quite important and poorly replaced by say movements of slides one after another).

However, all these presenting models have two major flaws which for the present purpose can be called “It is complicated,” on the one hand, or “It is oversimplified” on the other. This is so basically for two reasons; the business reality is far more complicated than the image shows, and pictures are here not just to replace 1000 words but also to emphasize what is crucial, leaving irrelevant issues aside. One should always keep in mind that the map presents itself. If it needs more words, then an educated viewer can infer for herself by simply looking at the image, then it is not map at all, and it creates more problems than it allegedly solves.

Two obvious flaws are as said too complicated visualization which becomes very unclear and hard to read and too simple visualization which is too clear as if there are no problems at all. Too complicated are such because they want to present all interconnections or overlap and failing to present typical patterns and too simplified are such because they want to reduce the complicated reality to few issues and failing to present again basic patterns of it. In order to show this point, let us observe the following illustration (see Fig. 1 below)

Some obvious flaws of typical presentations of stakeholder maps (as shown on Fig. 1) should be mentioned. First, all of them are good, useful, and efficient if there are only few stakeholders included and only few of their features (say needs or interest), but if there are many, the presentation loses its sense because it becomes too complicated and unclear which is shown by the amount of text needed in order to describe and explicate it. Second, diversity among stakeholders even if taken statically not to mention their dynamism say in time and/or relevance becomes invisible (even with the use of colors and arrows). Third, mutual relations among stakeholders become unique which is often not the case.

In order to bypass these and other shortcomings, there are different solutions. The first is to multiply the map in order to show different segments, say in business process or in segment of a company, or in risk or value of different stakeholders. The second is to combine different forms for different stages of a business process. For

Stakeholder Mapping, Fig. 1 Typical graphical presentations of stakeholder map. Depending on the point of view, the left column can be viewed as reality and the right as the presentation and vice versa

instance, for listing stakeholders, pie charts are suitable. Further on, listing and hierarchical order pyramids or a reverse pyramids are again quite useful. Then, for the groups of stakeholders and their relations Venn's diagrams are good, and finally grids are excellent for mapping the particular group of stakeholders. All these can be used and even placed above some timeline and additional presentation of various features of particular stakeholders, e.g., value, risk, interest, need, etc. However, such graphical presentations are not very regularly found in stakeholder map presentation (as noted before).

To cut long story short, it is important that the visualization fits not just the map, or the stakeholder management plan, but also an overall business plan. One should always keep in mind that visual aspect of a stakeholder map, i.e., its actual shape, size, divisions within it, colors, dynamics if present, etc., or what viewers and listeners of a plan who will apply it in practice are in the first contact with is the major influence on their concept of the whole stakeholder map. Namely, if a map represents quite dynamic system which will apply to a dynamic business activities and processes which could accommodate on weekly basis, then the visualization should be dynamic as well. As said, any map presents itself, but it points outside of itself, i.e., to the future practice (almost as a signpost that points to some direction or place, but does not go there), and therefore any map determines future practice, and so far as a SM is a map, it should do precisely that, no more and no less (it cannot do what is not in its nature or function).

Concluding Remarks

By presenting a stakeholder map, a SM process is finished, and its application is possible and precisely planned, i.e., stakeholder management plan can be executed to its end. However, no stakeholder map is an island (sometimes it is a peninsula). It is an integral aspect of a stakeholder management plan and stage of a process, which is a part of a business plan that includes managerial, financial, production, marketing, and other aspects. Therefore, consistency with all other aspects of a business plan and practice is important. Besides this complexity relation that is quite simple, there are other relations that are more complicated since they cut across various no matter if sometimes routine actions of a company, a profession, or even the whole business sector, such as SOPs, marketing procedures, management procedures, CSR (and CSI) procedures, etc.

One among such cross sections is obvious if one sees SM as a part not just of a stakeholder management plan and execution, and therefore of management aspect of a business plan, but also of a broader CSR plan which in its most

wide meaning includes all plans and executions related to business ethics, CSR, and sustainability (sometimes even to philanthropy, sponsorships, and similar). Because of these multidimensional relations of SM with other aspects of a business, every mistake in it can create unnecessary risks in many distant, different, and strange parts of a business, sometimes not even obviously connected to SM, stakeholder management plan, and execution, and these can and should be easily avoided by careful, quick, clear, and useful SM.

Summary

In this entry, stakeholder mapping (SM) is presented. The importance of SM is emphasized given their principal conceptual clarity and division, as well as their presentation, in most cases graphical and dynamical. SM is the first step of the ethical dilemmas solutions, and of the decision-making process under the view of CSR, legality, and profitability.

Background

Modern companies are very different from the primitive factory model “when the typical corporation owned and operated a canal, a railroad, or a big manufacturing plant” (Blair 1995, pp. 232–233). A company consists of not only equity capital but also other financial and non-financial resources, and its wealth-generating increasingly

depends on various different types of resources contributed by various stakeholders (Blair and Stout 2006). In short, the company needs the support of all its diverse stakeholders in order to sustain and prosper. As Freeman’s (1984) seminal book *Strategic Management* demonstrated 30 years ago, ignoring stakeholders would give rise to disastrous consequences. In order to obtain their support, what is fair and essential is to take the interests of stakeholders into account. Especially, given today’s competitive economic environment, the only viable way to preserve competitive advantage and profitability is to encourage every corporate stakeholder to make a wholehearted contribution.

Human capital or intangible investment made by stakeholders is of increasing importance, whereas shareholders’ role becomes less important. Even for manufacturing companies which were heavily dependent on physical plant and equipment invested by shareholders, the intangibles contributed by stakeholders such as intellectual property, brand reputation, service capabilities, and alike make up a rapidly increasing share of the assets (Blair 1995). There is also a simultaneous trend that shareholders are more willing to be *passive and functionless investors* instead of *active participants*, concerned only with receiving “a return on their capital accruing with the mere passage of time” (Ireland 1999, p. 42). This indicates they would come to be more opportunistic and apathetic. As Professor Ireland (1999, p. 54) aptly notes, “the great majority of share dealings involve not issues raising capital for new investment but the buying and selling of titles to revenue issued long ago.” Most shareholders, including institutional investors, only put an insignificant amount of their money into any individual company in terms of a diversified portfolio strategy, and they are not committed to a company in either a moral or practical sense (Green 1993). The role of equity and physical capital in investment “is much less important than it was” in modern public companies at present (Kay 2012, p. 25). Based on Berle’s observation that shareholder investment by way of purchasing stock does not contribute savings to a company or undertake the residual risk of a new/increased economic operation in the preface

to the revised edition in 1968 (Berle and Means 1991), Professor O'Sullivan (2001, p. 49) further points out:

Shareholders in these economies generally invest their money in the securities issued by successful enterprises on the basis of investments in productive assets that have already been made. In other words, public shareholders do not 'wait' until the developmental investments that these companies make bear fruit but buy shares in these companies after they have paid off.

Meanwhile, Professor Deakin (2005, p. 15) argues that "[m]ost trades of shares in listed companies consist of movements from one shareholder to another with no new capital being supplied to the company." It is believed that net contribution of new equity to the corporate sector has become negative. By contrast, stakeholders' firm-specific investment is, on the one hand, much greater (e.g., Williamson 1984) and, on the other, more valuable (e.g., Zingales 2000) than the financial investment.

Consequently, for large public companies, which are of course "mature" enough, the contribution made by stakeholders and the role performed by them is obviously no less important to corporate success. Shareholders are not materially different from any other stakeholder group as a resource provider. They are not the only group which bears residual risks, since stakeholders suffer as well when the company runs badly. In fact, shareholders can take advantage of diversification to reduce and dilute idiosyncratic risks, while other stakeholders cannot. Shareholders are not the only residual proprietary claimants either (Yan 2015). Any increased earnings, namely, the residual, may go to the creditors when the company cannot afford all of its debt. Even in a well-run company, the residual can go to employees as bonuses or go to customers in the form of improved service, instead of directly going to shareholders as dividends (Zingales 2000). It is then obviously inappropriate to overstate the role and importance of shareholders, especially in a large public company (Blair 1995). The argument that stakeholders have a right to be treated as an end rather than a means is therefore worth considering seriously. By virtue of the stakeholders'

important role and intrinsic value, their interests should not only be an instrument serving as a means for long-term shareholder interests.

Definition

As an alternative model for corporate objective, stakeholder theory is antithetical to the shareholder model and requires directors of the company being *accountable to* more than the shareholders, namely, directors should take interests wider than shareholders into account. While the origin of "stakeholder" is difficult to trace, it is generally agreed that the term did not formally appear until 1963 (Freeman 1984). Stakeholders first meant "those groups without whose support the organization would cease to exist" such as shareholders, employees, customers, suppliers, and so forth (Freeman 1984, pp. 31–32). With continuous evolution, it is broadly defined as "any group or individual who can affect or is affected by the achievement of the organization's objective" (Freeman 1984, p. 46). Stakeholder theory as a theory of the firm is intended to "explain and guide the structure and operation of the established corporation" (Donaldson and Preston 1995, p. 70). Generally speaking, a company is viewed as an entity through which various participants accomplish multiple purposes, thereby ensuring the interests of those with a stake in companies are taken into account and not automatically subordinated to any other group's interests (Yan 2017). And accordingly, the company should create value for all stakeholders rather than solely for shareholders.

Justification

Based on Donaldson and Preston's (1995) categorization of descriptive, normative, and instrumental aspects of the theory, we can see the descriptive aspect of the stakeholder model explains what the company is and how it operates in order to predict future corporate behavior. As summarized, stakeholder theory has been used to describe the following: "(a) the nature of the firm, (b) the way

managers think about managing, (c) how board members think about the interests of corporate constituencies, and (d) how some corporations are actually managed” (Donaldson and Preston 1995, p. 70). As John Kaler (2003) argues, being descriptive explains the reality of business, it is “about making a factual claim about a theory” (p. 73). The descriptive stakeholder theory is based on its descriptive accuracy.

The normative stakeholder theory emphasizes the intrinsic value of stakeholders and acknowledges that the shareholder’s role is not materially different from that of other stakeholders – they are simply one group of resource investors/providers (e.g., Donaldson and Preston 1995; Handy 1991). Each stakeholder agrees to put her valuable resources, labor, or both together with others’ to pursue the success of the business and derive benefits from it. For example, Freeman et al. (2004) argue that “business is about putting together a deal so that suppliers, customers, employees, communities, managers, and shareholders all win continuously over time” (p. 365). The morals and values perceived as fundamental to running companies, including fairness, are emphasized (Phillips 1997; Phillips et al. 2003). Meanwhile, the welfare of all stakeholders cannot be unaffected by the performance of the company. By the words of Janet Williamson (1996, p. 212):

Employees are affected by the wide range of decisions the impact upon their employment with the company; customers are affected by decisions on the price, specifications and standards of products; suppliers are affected by purchasing decisions; creditors are affected by financial procedures; and the local community is affected by recruitment policy and environmental impact. . . .

Like shareholders, stakeholders’ investment could also be at risk. For example, when a company is badly run or becomes insolvent, creditors may not get back the loan as well as the interest, and employees may be made redundant. They have an interest in the company – in Freeman’s (1984) term, each stakeholder has a stake in the company. And these stakeholder groups cannot obtain enough, if any, protection via an incomplete contract by virtue of unbalancing bargaining power, informational asymmetry, and/or bounded

rationality. Corporate decisions can lead to significant social consequences by affecting others and the economy at large (Parkinson 1993). Due to its involvement and influence in various aspects of social life, a large public company is expected to be more aware of social obligations including fairness, justice, and the like (Letza et al. 2004).

It thus implies that directors’ duties and accountability should not be limited to ensuring returns to shareholders, but extend to those who are interested in, and affected by, the company and whose role is no less significant (Allen 1992). Furthermore, under certain situations, so the argument goes, directors are even required to possess “a willingness to exhaust the resources of the company” to satisfy stakeholders’ interests (Green 1993, p. 1421). Accordingly, the shareholder-centered model is criticized for “using the *prima facie* rights claims of one group — shareholders — to excuse violating the rights of others” (Freeman et al. 2004, p. 365). Opponents of the shareholder model point out it damages other stakeholders’ interests and argue that the shareholders as one group of corporate constituents have no reason to automatically override other groups’ interests. In the context of the stakeholder model, every stakeholder has a right to be treated as an end and not simply a means to facilitate the shareholder profits (Donaldson and Preston 1995; Freeman 1984). Accordingly, reputation, positive relationships with customers and suppliers, and motivated employees are not just for fostering the business goals of increasing shareholder value as in the context of the shareholder model. All stakeholder interests should be considered by directors of the board, even if they go against shareholders’ sectional interests. Treating stakeholders as an end means they are no longer merely a means for maximizing shareholder wealth; instead, stakeholders’ welfare should be seen as an ultimate and intrinsic objective of the company (Freeman and Phillips 2002).

In contrast to the normative stakeholder theory’s emphasis on moral values and fundamental human rights, instrumental stakeholder theory focuses on how stakeholder value can be used as a means to improve corporate performance. It finds the stakeholder model is more economically

efficient than its rival approach. First, it recognizes that companies are not able to succeed or achieve business goals in the absence of stakeholders' contribution, whether pecuniary or non-pecuniary. Apart from shareholders, other non-shareholding stakeholders' investments, such as the credits provided by creditors, the labor and know-how provided by employees, the services and products provided by suppliers, and the infrastructure provided by the government among others, are indispensable. Secondly, as Thomas Jones (1995, p. 432) observes, there is a distinct competitive advantage:

This instrumental theory of stakeholder management essentially turns the neoclassical theory of the firm upside down. It implies that behaviour that is trusting, trustworthy, and co-operative, not opportunistic, will give the firm a competitive advantage. In the process, it may help explain why certain 'irrational' or altruistic behaviours turn out to be productive and why firms that engage in these behaviours survive and often thrive.

Put differently, the stakeholder model is argued as beneficial to fostering both existing and future contributors' potential, which subsequently helps advance aggregate wealth (Keay 2010). The internal logic is that the shareholder model would damage other stakeholders' incentive by virtue of their inferior position vis-à-vis shareholders. They might worry about being subordinated by shareholders' interests. This may also explain claims that the stakeholder model is – in contrast with the argument from a traditionally pure ethical perspective – a key to allowing businesses to make more profits (Campbell 1997). When stakeholders know their interests will be adequately considered by corporate management during the corporate decision-making process, they will be more likely to invest in that company and “go the extra mile.” Specifically, creditors may charge a lower interest rate or lend more when they are confident that it would be safe to put money into the company, employees may be more loyal to the company and work more passionately and productively, suppliers may also be more willingly to make firm-specific investment, and so forth. While shareholder model advocates insist that stakeholders would be better off under

the maximization of shareholder wealth (e.g., CLRSG 1999), stakeholder model advocates doubt its validity and believe that such an approach may not necessarily benefit other stakeholders or society as a whole (e.g., Dodd 1932). The lopsided focus on shareholder interests could be easily conducive to negative externalities, such as transferring costs of the company to stakeholders and retaining benefits for shareholders (Lee 2006).

Summary

A good company should provide a fair return to its shareholders, deliver quality products and services to consumers, build a good relationship with suppliers, take care of creditors' interests, improve job security and welfare for employees, and contribute to the well-being of the local communities and the prosperity of society. A narrow, shareholder-focused approach is increasingly more difficult to justify as a suitable guide for directors and their delegated managers in a company.

Influence group analysis; Key actors analysis; Stakeholder perspective approach

Definition

Since the announcement of corporate social responsibility (CSR) concept in around 1950s, the scholars have tried to “unearth” the true meaning of CSR and have used several perspectives or approaches. One of the approaches that has significant role in examining and identifying the role of business in terms of its relationship with society is stakeholder approach. There are many theories and concepts in this approach, trying to decode the

relationship between the company and society and how both of party can influence one another.

To understand the stakeholder approach, first we must understand the meaning of the term “stakeholders.” Freeman gives a very broad definition: “a stakeholder in an organization is (by definition) any group or individual who can affect or is affected by the achievement of the organization’s objectives.” The groups or individuals, who are related to or affected by business, are commonly referred to as stakeholders. They are the following: the employees, customers, shareholders, suppliers, the local community, and the society at large (Freeman and Mcvea 2001). Jones and Wicks (1999) offers three typologies that he has extracted from the academic scholars in defining the stakeholder approach which are normative, instrumental, and descriptive/empirical.

These early formulations suggested (often simultaneously) that (1) firms/managers should behave in certain ways (normative), (2) certain outcomes are more likely if firms/managers behave in certain ways (instrumental), and (3) firms/managers actually behave in certain ways (descriptive/empirical) (Jones and Wicks 1999).

Normative stakeholder theory or also known as “narrative interpretation” is a theory which explains that the moral behavior is the foundation, in the contexts of engaging stakeholders. Rather than focusing on data or evidence, this theory focuses on normative issues such as moral obligation. While instrumental theory is contingent theory, the predicted outcomes are contingent on behavior of a certain type. It does not require the theorist to make simplifying assumptions about the fundamental nature of human behavior, such as the assumption of self-interest (or opportunism) made by economists (Jones and Wicks 1999). Lastly empirical or descriptive theory focuses in describing the actual behavior of the manager.

Post et al. (2002) argued that the stakeholder theory accentuated the notion that corporations must be viewed as operating at the center of a “network of interrelated stakeholders that create, sustain and enhance value creating capacity” (Post et al. 2002).

Introduction

The emergence of corporate social responsibility (CSR) concept in the business scene since around 1950s has highlighted the intertwined and reciprocal relationships between business and society. Although the search of the “true meaning” of CSR is still ongoing to this day. Scholars have tried to formulate the concept of CSR.

There are two factors that need to be understood in understanding strategic CSR, that is social responsibilities and social issues. Social responsibilities refer to the expectations that society put on companies while social issues refer to the factors where the given responsibilities are tied. Said factors, beside affecting companies’ ability to meet its objectives, can also affect their social responsibilities. Scholars suggested that there are two sides of the social contract: “formal”, which refers to firm’s explicit responsibilities such as obeying laws and regulations, creating jobs, paying taxes, etc., and “semiformal” contracts that refer to society’s implicit expectations towards the companies (Galbreath, Building Corporate Social Responsibility into Strategy, 2009).

Galbreath (2006) came out with 4 (four) strategic options to conceptualize CSR. Four strategic options are described, including: the shareholder strategy, the altruistic strategy, the reciprocal strategy, and the citizenship strategy. In the shareholder strategy, CSR is merely a component of an overall profit motive, the focus of the companies is only maximizing shareholder returns. While in altruistic strategy, interwoven relationship between the firm and its community is acknowledged and understood where the companies felt as they are a part of the community and must give back for the greater good of community (Galbreath 2006). Moving forward to reciprocal strategy when relationship goes beyond feeling and formal partnerships is involved for example between the firm and specific community group or nongovernmental organizations (NGO). While citizenship strategy goes further in recognizing various stakeholders, who are related to or impacted by the business, they must admit that stakeholders have different interests and expectations, and therefore there should be different

approach to engage. This is known as a stakeholder approach.

The term stakeholder started to emerge in around 1960s, pioneered by Stanford Research Institute (now SRI International). The stakeholder approach in CSR scene emerged in around 1980s.

One of the prominent scholars on the stakeholder approach was Edward Freeman, who wrote in his article about strategic management – A Stakeholder Approach in 1984. He offers the following characteristics of stakeholder approach, namely (Freeman and Mcvea 2001):

1. A stakeholder approach is intended to provide a single strategic framework, flexible enough to deal with environmental shifts without requiring managers to regularly adopt new strategic paradigms.
2. A stakeholder approach is a strategic management process rather than a strategic planning process. Strategic planning focuses on forecasting how the environment would be in the future, followed by independently developing plans for the firm to exploit its position.
3. The central concern of a stakeholder approach is the survival of the firm, seen in Freeman's words as "the achievement of an organization's objectives". Management must direct a course for the firm, not only trying to optimize current output, and that's how the company survive unstable environment.
4. A stakeholder approach encourages management to develop strategies by looking out from the firm and identifying, and investing in, all the relationships that will ensure long-term success. This emphasize on critical role for values and "value-based-management" within the business strategy.
5. Stakeholder approach is both a prescriptive and descriptive approach, rather than purely empirical and descriptive. This encourages strategic management that integrates economic, political, and moral analysis. This approach will have impacts on research in the discipline as well as practical results for managers.
6. The stakeholder approach is about concrete "names and faces" for stakeholders rather

than merely analyzing particular stakeholder roles. This calls for the management to delve in understanding of who are the real, concrete stakeholders specific to the company, and the circumstances in which it finds itself.

7. A stakeholder management calls for an integrated approach to strategic decision-making. Managers should find ways on fulfilling the needs of multiple stakeholders simultaneously rather than set of strategy stakeholders by stakeholders; strategies that integrate all stakeholders' perspective rather than offsetting one against another.

This characteristic shows embeddedness between stakeholders of the company with the company's management. SRI International then stated that it is important for managers to understand shareholders, employees, customers, suppliers, and society general so that the company can have the objectives that are supported by the stakeholders. In return, the company can achieve long-term success because the support from stakeholders would likely to help the business to sustain. This also suggests that managers should go all out in exploring their relationships with all stakeholders in order to develop business strategies.

Stakeholder approach has been used in developing the CSR strategy of the company. In this regard, companies not only have the social responsibility to fulfill but it also has to respond to the needs of specific constituents who are related to or impacted by their business. New developments also showed that because the advancement and acknowledgement of CSR keep growing since 1950s, stakeholders' (e.g., society, customers, etc.) expectations have evolved dramatically. It would be difficult to determine what are those responsibilities or moral obligations that based these responsibilities when the ones who have the obligations are unclear.

Therefore, it is so critical to have the clear definition of stakeholder, at least in terms of managerial implementation. However, usually the definition could be too broad, and it makes it difficult for the companies to understand the impacts of certain stakeholders to their organization/

company. Therefore, not only should the definition be sufficiently comprehensive and not too inclusive, but also should be clear enough to avoid misinterpretations. Stakeholder analysis tools, such as stakeholder mapping, power/interest matrix, and stakeholder moral responsibilities' matrix have been developed to provide a practical framework for managers (Kakabadse 2005).

To help determining certain impacts of certain stakeholders to the companies, Phillips (2003) offered an approach that highlight stakeholder's legitimacy. He argued that there are three types of stakeholders based on their legitimacy, which are: normative, derivative, and nonstakeholders. He suggests that normative stakeholders are those stakeholders to whom the company has a moral obligation, an obligation of stakeholder fairness, over and above that due other social actors simply by virtue of their being human. Meanwhile, derivative stakeholders are those groups whose actions and claims must be accounted for by managers due to their potential effects upon the organization and its normative stakeholders (Phillips 2003). Lastly, there are groups who are not considered as stakeholders at all and to these groups, the company has no moral obligations or responsibilities, as they also do not really have an impact to the company.

However, it should be noted that distinguishing clearly various categories of the stakeholders would be difficult. In certain circumstances, non-stakeholders can shift to derivative or normative stakeholders. The normative bond between a stakeholder group and company might be broken so that what used to be a normative stakeholder can become nonstakeholders. Or in some cases, a person of a stakeholder group can stop being a member of that group thus no longer a stakeholder.

Essentially, some of these stakeholders will have more influence than others and the business must have an understanding of how much influence and power each of these stakeholder groups have at present and also in the future (Papasolomou and Krambia 2005). Due to this imbalance power that is distributing around the stakeholders, the enthusiasts of this approach proposed that corporate managers have the task to

balance the interests of the different groups who are affected by or related to the business. The needs to balance these interests of the stakeholders demand the corporate to form the policy based on the perspective of all stakeholders.

When thinking about stakeholders, it should be noted that they have to be managed over the long run. Harrison and St. John, (in Freeman and Mcvea 2001), differentiate two basic posture on stakeholder management, that is: buffering and bridging. Buffering is the traditional approach for most "external" stakeholder groups, and it has objective at containing the effects of stakeholders on the firm. This approach includes several activities including market research, public relations, and planning. While buffering draws the line between the company and its external stakeholders, recognition of common goals and blurring the lines around the organization is required in bridging approach, and it involves interdependence and proactive partnering (Freeman and Mcvea 2001). This approach proposes a framework for determining the importance of developing partnering tactics and to rely on more traditional methods when it is convenient.

Key Issues

In the field of corporate social responsibility (CSR), relationship between companies and their stakeholders always spark interest both in academic community and among the company managers. The managers are aware of the diversity of legal norms, standards, practices, and CSR needs for a country, region, or line of business and of the fact that local managers are subject to constant pressure from stakeholders in order to enhance their involvement in CSR (Idowu et al. 2018). Stakeholders are consisted of various individuals or groups that have different needs and expectation toward the company and impose different interest.

Since the birth of stakeholder approach in business management area, it is a difficult task for managers to make attempts on balancing the interests of these different groups and individuals

which might also have possibilities to stand up against each other. Not including or refusing one of the identified interest or expectations of stakeholders when developing the objective may cause in backlash from the certain stakeholders which can hurt the business. However, companies tend to be socially perceived as responsible for certain stakeholder, for example, local community, and this could also raise criticism from different stakeholder groups.

Although, the stakeholder approach can help company managers to understand the relationships of the companies with their constituencies who are involved in their activities in various levels, it does not independently offer means or tools to capture the quality of these relationships. It would not be able to help the managers to understand forces that influence these stakeholder's expectations or the power and bargains of the stakeholders. This makes it difficult for the managers to identify or assess the potential threats that stakeholders might possess against the objectives of the companies.

Some scholars also argued that stakeholders approach is ill-spirited as it tends to imply the needs to sacrifice the business objectives of the organization, for example, generating profits for other social goals that could be not sustainable economically in order to be accepted by the stakeholders. Meanwhile the true purpose of the stakeholder approach is not to ignore or reject the company's business purposes, such as gaining profits, but rather broaden the shareholder model.

Another issue emerges when the definition of stakeholders is too broad and it affects the scope of the stakeholders in the business, it opens the possibility to include stakeholder groups or individuals that would likely to harm the company rather than support it, for example, the group that has tie-up with the competitors. While, managerially, stakeholders theory would not be complete without the existence of competitors in considerations, the company is not managed for the benefit of the competition.

Because the stakeholder approach put the attention on stakeholders' expectation, it should be noted that their expectations are not always in

line with the existing rules or law. When the aspirations from larger society that are represented through stakeholders are not met, there are potentials that society will impose their aspirations by going beyond the law.

These expectations or demands might come from considerations of what is sometimes disparagingly called conventional morality. Ignoring or not taking any claims into account when applying ethical norms to business, society, and stakeholders can still constrain business in a various ways other than by law, for example, by practicing social pressure and moral sanctions (such as boycotts, defamation of company brand image, or publicizing harmful corporate actions), thus these kind of repercussion should be anticipated by really listening to what the stakeholders might have in their aspiration by also keep informing the society with the good deed that has been done through the reports and other communication means.

Summary

Stakeholder theory has significant role in examining and identifying the role of business in terms of its relationship with society. There are many theories and concepts that in this approach are trying to decode the relationship between the company and society and how both of party can influence one another. To understand the stakeholder theory, first we must understand the meaning of the term "stakeholders." Freeman gives a very broad definition: "a stakeholder in an organization is (by definition) any group or individual who can affect or is affected by the achievement of the organization's objectives,"

To be able to understand this approach, Edward Freeman offers the characteristics of stakeholder approach, i.e., (1) providing a single strategic framework; (2) management process rather than a strategic planning process; (3) the survival of the firm; (4) encourages management to develop strategies; (5) prescriptive and descriptive; (6) concrete "names and faces;" and (7) calls for an integrated approach to strategic decision-making.

Stakeholder approach has been used in developing the CSR strategy of the company. In this regard, companies not only have the social responsibility to fulfill but it also has to respond to the needs of specific constituents who are related to or impacted by their business. However, there is imbalance power that is distributing around the stakeholders, thus this approach proposed that corporate managers have the task to balance the interests of the different groups who are affected by or related to the business. It also should be noted that their expectations are not always in line with the existing rules or law. When the aspirations from larger society that are represented through stakeholders are not met, there are potentials that society will impose their aspirations by going beyond the law.

Although the stakeholder approach can help company managers to understand the relationships of the companies with their constituencies who are involved in their activities in various levels, it does not independently offer means or tools to capture the quality of these relationships. This makes it difficult for the managers to identify or assess the potential threats that stakeholders might possess against the objectives of the companies.

Stakeholder Thinking

Synonyms

[Stakeholder framework](#); [Stakeholder model](#)

Definition

The definition of “stakeholder thinking” comes from the first definitions of stakeholder and the birth of stakeholder theory by Freeman. Indeed, even if the stakeholder concept found its roots in

the works of Rhenman and Stymne (1965) in Sweden and Ansoff (1965) in the United States, the concept became popular thanks to Freeman's publication of 1984.

"Stakeholder" is at the center of stakeholder thinking. Hence the meaning of "stake" and "holder" is important within the stakeholder thinking. Simple, the word "stake" means a right to do something in response to any act or attachment. Since, rights are generally attached with liabilities, this word also denotes liabilities of someone for enjoying a particular right. A stake could be a reasonable share of something. From the organizational stakeholder perspective, Carroll identifies three sources of stakes: ownership at one extreme, interest in between, and legal and moral right at the other extreme. The word "holder" is comparatively easy to understand. It denotes a person or entity that faces some consequences or need to do something as a consequence of act or to meet a certain need. Combining these two sets of meaning, stakeholder can be defined as "any group or individual who can affect or is affected by the achievement of the firm's objectives." For instance, the employees, customers, investors, competitors, government, and non-governmental organizations (NGOs) can be the stakeholder of a company (Rahim 2015).

Key Issues

Stakeholder thinking is a concept that has grown over time as fields such as business ethics, business and society, corporate social performance, and strategic management.

Freeman, generally known as the founder of the Stakeholder theory, in his work "Strategic Management: A Stakeholder approach" (1984), considered the company at the center of many interactions between stakeholders.

Carroll extended the interest in stakeholder thinking by authoring a business and society textbook and subsequent editions using the stakeholder approach (1989, 1993, 1996).

In the theoretical context of stakeholder theory, different stakeholder groups interact with company.

Stakeholders are defined as persons or groups that have, or claim, ownership, rights, or interests in a corporation and in its activities, past, present, or future. Stakeholders with similar interests, claims, or rights can be classified as belonging to the same group: employees, shareholders, customers, and so on (Clarkson 1995).

In literature, however, there are many definitions of stakeholders (Mitchell et al. 1997), all of which share their roots in the definition from Freeman (1984): "Any group or individual who can affect or is affected by the achievement of the organization's objectives."

Stakeholders might also be constructed in categories such as primary vs secondary, active vs passive, economic vs social, core vs strategic.

Literature offers different proposals to classify stakeholders by their respective level of importance, as resumed in the following table by Mainardes et al. (2012) (Table 1).

The corporation success depends on the managers ability to create satisfaction for each stakeholder group, so that each group continues as a part of the corporation's stakeholders system.

Stakeholder Thinking, Table 1 Stakeholder classification typologies

Authors	Classification/criteria used
Goodpaster (1991)	The strategic and the moral stakeholder
Savage et al. (1991)	Stakeholder's potential powers to threaten or cooperate with the organization
Clarkson (1995)	The primary (with formal relationships) and the secondary (without formal relationships)
Mitchell et al. (1997)	Power, legitimacy, and urgency
Rowley (1997)	Network density and the centrality of the organization focus
Scholes and Clutterbuck (1998)	Power of influence, impact on the organization and affinity with organizational objectives
Kamann (2007)	Power and the level of interest
Fassin (2009)	Classical stakeholders, stakewatchers, stakekeepers

Mainardes et al. (2011)

Donaldson and Preston (1995) have argued that the stakeholder approach is useful for descriptive, normative, and instrumental reasons. Thus, the power of stakeholder thinking is extended beyond its usefulness in describing organization relationships. The dual dimensions of stakeholder thinking, such as ethical and strategic one, have been discussed by Goodpaster (1991).

Five questions should be asked by managers to capture the information essential for effective stakeholder management: who are my stakeholders? What are their interests? What opportunities and challenges do the stakeholders present to the firm? What responsibilities does the organization have to its stakeholders? What strategies or actions have to be implemented by firms to respond to stakeholders' requests? (Carroll 1996).

The stakeholders, being among the main protagonists of corporate life, feel the need to be integrated and contribute to improving the company in which they are involved. Therefore, stakeholder engagement (SE) becomes a composite process that includes more methods of interaction consultation, communication, exchange, and dialogue between the company and its stakeholders. Greenwood (2007) identifies SE as the set of procedures that an organization develops to involve stakeholders in organizational activity, in order to create a system of cooperation (Phillips 1997).

Stakeholder theory scholars have tried to classify the relational models between organizations and stakeholders by assuming a gradual growth of stakeholder involvement and participation. First, the organization identifies and maps its stakeholders, if possible distinguishing between primary parties (those who are strategic in the middle to long term) and secondary parties (stakeholders that do not affect its sustainability) (Clarkson 1995). Second, it tries to manage stakeholders' expectations and the claims they support in accordance with their salience (Mitchell et al. 1997), while also balancing these various positions through a process of stakeholder management (O'Dwyer 2005). In the last step, organizations try to engage primary stakeholders in decision-making processes, making them participants in organization management and governance, sharing information, dialoguing, and creating a model of mutual responsibility. The

stakeholder engagement phase, unlike the stakeholder mapping and management phase, "creates a dynamic context of interaction, mutual respect, dialogue and change, not a unilateral management of stakeholders" (Andriof et al. 2002). As a result, the main feature of stakeholder engagement is not to encourage the mere involvement of stakeholders to "mitigate" or manage their expectations, but to create a network of mutual responsibility.

Future Directions

Undoubtedly, nowadays, stakeholder theory could not develop enough understanding of the heterogeneity of stakeholder claims and interests in focal firms. More importantly, the common or generic categories of stakeholders – for example, suppliers, customers, shareholders – are considered inadequate because they do not offer a realistic portrait of the stakeholders that interact with firms. Additionally, stakeholder theory is silent on what occurs when these generic categories breakdown (Freeman et al. 2010). This silence limits the ability of stakeholder theory to prioritize stakeholder claims. Building on stakeholder salience, Perrault (2017) proposed "status" as an attribute that explains how managers assign salience to various stakeholders and attempts to define how stakeholder claims are prioritized based on their status. Perhaps the first step for future research on this connection would be to empirically examine Perrault's (2017) proposition of the relevance of status with stakeholder salience and other salience attributes, for example, power and legitimacy. Knowing how status translates into power and how stakeholders possessing different levels of status push their claims on focal firms should provide important knowledge for this field. Within the broader premises of the stakeholder theory examining the associations between status and power and between status and legitimacy would be helpful to understanding negative, additive, subsuming, and synergistic results.

Moreover Crane et Ruebottom (2012) proposed an adaptation to stakeholder theory whereby stakeholders are conceptualized on the basis of their social identity. They proposed an

alternative approach based on the notions of social identity, as the fundamental key for group cohesion, mobilization, and action.

Previous research has suggested that, apart from the originally proposed attributes of salience (Mitchell et al. 1997), proximity (Driscoll and Starik 2004), frequency of contact (Luoma-aho 2005), status and organization (as discussed above) also determine stakeholder salience. The attribute of proximity is relevant to modern organizational forms and to not-for-profit organizations because they build more on networks and coalitions (Yaziji and Doh 2009). Khurram et al. (2019) believe that there is a need to empirically examine the proximity and frequency of contact to be attributes of stakeholder salience. Moreover, a detailed effort should also be directed toward untangling these attributes and drawing conceptual boundaries that differentiate between the two.

Nowadays, a stronger general equilibrium analysis that better incorporates dynamic aspects of the stakeholder salience model is necessary. Future research should investigate the salience and importance of stakeholders considering the dynamic relationship between a company and its stakeholders, also in light of the greater and greater importance given to digitalization.

Definition

Stakeholder Value Creation (SVC) is a decision-making approach based on the premise that business success is dependent on its ability to inclusively create collective value with and for multiple stakeholders. While still evolving, SVC emerged from the realization that an over-emphasis on shareholder dominance is harmful to society and the environment (Hampden-Turner et al. 2019a, pp. 28–37). In contrast with the short-term, profit-maximizing emphasis of shareholder value creation strategies, when making wealth-generation choices, corporate decision-makers increasingly embrace the rationale of stakeholder theory. SVC signifies a shift toward sustainable strategies driven by entrepreneurial purpose.

Both the novelty and the comprehensiveness of the SVC concept signify a broadened approach to business decision-making. This necessitates the realization of a new purpose and role for business at both the macro-, and microlevel of the organization's operating environment. At microlevel, SVC profoundly impacts an organization's *raison d'être*. Transitioning from an isolated shareholder value perspective to fundamentally creating integrated optimized value via an inclusive stakeholder-orientated approach significantly broadens the potential for the role of business in society. This unleashes innovation so that sustainable strategies evolve from being focused exclusively on environmental matters or the responsibility of governments or individual companies, to becoming a *connected endeavor* (Jonker and O'Riordan 2016, p. 5; O'Riordan 2017, p. 165).

Stakeholder relationship management

Explication of Related Concepts

Stakeholder Theory goes beyond the traditional narrow shareholder view of management, which emphasizes the exclusive interests of shareholders. Based on the premise that exaggerating the interests of one group depletes the overall value created by and for the entire alliance, stakeholder thinking advocates a decision-making approach, which collaboratively, inclusively, and concurrently realizes a broad and multiple range

of collective stakeholder interests (O’Riordan 2017, pp. 59–61). Because this approach includes the interests of shareholders, by definition, it incorporates the shareholder value creation perspective (see ► [“Stakeholder Theory”](#)).

Stakeholders are defined as those groups and individuals who can affect or are affected by the achievement of some intended purpose (adapted from Freeman 1984, p. 52). Stakeholders are broad-ranging in scope because they comprise all those parties who potentially impact and/or are impacted by the choices made by those decision-makers aiming to realize some chosen objective (see, for example, Greenwood 2007; Mitchell et al. 1997, pp. 853–854; O’Riordan and Fairbrass 2008). Culminating in a comprehensive network of potential “players,” stakeholders can derive from the macro-, and/or microenvironment of an organization’s operating context. The relevant groups and/or individual stakeholders requiring consideration by decision-makers in the pursuit of some intended purpose is context-specific, i.e., dependent on the circumstances of each venture or purpose (O’Riordan 2017, p. 61). This topic is addressed in a separate entry written by the author in this Encyclopedia (see ► [“Stakeholders”](#)).

Stakeholder Relationship Management or Stakeholder-Orientated Management constitutes a range of formal and informal corporate activities focused on solving social and environmental challenges. The premise that relationships are the key to synergy and sustainable harmony advocates architecting stakeholder interests into products and services already at their conception and design stage. The underpinning rationale for this approach comprises the “Triple Bottom Line” (Elkington 1997, p. 2), and more recently, the “Triple Top Line” concept proposed by McDonough and Braungart (2002). Together, these concepts recommend regarding stakeholders in both the top line (sales) and the bottom line (profits) strategy (see ► [“Triple Bottom Line”](#)).

The conscious inclusion of stakeholder interests into the business operations of the firm can include managing stakeholder relationships via policies, practices, and programs. It can include

activities such as stakeholder prioritization and other choices about how to engage with stakeholders for the ultimate PURPOSE of generating economic, social, and ecological values. Sustainable strategic relationships ensue relating to the decision-making processes of planning, leading, organizing, implementing, and controlling the organization’s engagement with stakeholders within the business. This approach additionally includes operationalizing the corporate strategy into business functions, such as: production, marketing, accounting, and personnel management. Developing stakeholder relationships triggers the requirement to engage with stakeholders (see ► [“Stakeholder Relationship Management”](#)).

Stakeholder Engagement is defined as an inclusive approach to business practice by involving Stakeholders in a positive manner in organizational activities to achieve mutually acceptable outcomes (Greenwood 2007). It comprises establishing, developing, and maintaining stakeholder relations. This includes stakeholder identification, consultation, communication, dialogue, and exchange. It highlights how companies must “remain relevant” to stakeholders to survive in a challenging business environment. It emphasizes how “being relevant” requires regular interaction with important stakeholder groups (Greenwood and van Buren 2010). Stakeholder Relationships thus require a mindset shift, which views the organization as one party in a network within communities at all levels of Society from global to national (e.g., countries), to local (e.g., cities) and business communities (e.g., consumers, investors, minorities, etc.). This further entails managing the individual and collective expectations of those stakeholder groups.

Conceptual Foundation and Historical Development

The question of how to create value is related to philosophical reflections about how to lead a “good life.” Debates on how to best achieve “prosperity” are inspired by varying perspectives on how to realize the full development of each being’s “natural” potential. Such discussions have

been ongoing since the height of Greek philosophy in the fifth century BC. They have always been inherently linked to considerations about the synergies of success and responsibility, which were viewed by Aristotle as two sides of the same coin (Ross and Brown 2009). In the Middle Ages, this way of thinking was incorporated into Christianity where it was combined with Christian notions of the good life and how people (should) interact with one another. The Charity Commandment “love thy neighbor as thyself” (Matthew 22: 39 2011) advises individuals to include others in their considerations in the pursuit of any activity. [For clarification: “others” means: all individuals in the sense of “anyone” and not merely “others like me.” This advocates the inclusion of all (human) beings regardless of potential perceived “differences” based on mental constructs. This principle assumes equality on matters including gender, race, and sexual orientation, among others. Moreover, the circularity of this commandment reminds us that to reach our full potential, we must both receive love and give it to others in a cyclical way]. Other religions adopt similar notions, such as Daoism, which is related to Confucianism, and the principle of Dharma in Buddhism. These generally view the notion of being “responsible” to “others” as the first step on the path to “enlightenment.” The rationale for these assumptions is based on the unified view that every (human) being is sacred (or created in the image of God as believed by Christian religions), and therefore entitled to “love.” This is paralleled in the Greco-Christian notion of *agape*, meaning to embrace a universal, unconditional love, which transcends and persists regardless of circumstance (Nygren 1953). Notwithstanding the origin, these principles advocate that every being is unequivocally sacred. More universally, going beyond the theological view, they form the origin of humanism exemplified by Erasmus in his correspondence with Luther (Erasmus Centre 2019), and Thomas More in his book: *Utopia* (More 2016). These notions could be considered as the forerunners of an attitude, which reasons that every individual deserves consideration when undertaking any chosen activity (O’Riordan 2017, p. 4).

They could accordingly be interpreted as the early precursors for stakeholder theory.

The above review of the philosophical quest for “utopia” in a social context (society) presents the early foundations for modern-day thinking on Human Rights and the concept of “good citizenship.” The reflections of the early Greek philosophers, as well as the diverse deliberations of various theologians and humanist advocates, remind us that we are all “united” under the same principles to “love” our “neighbour.” This rationale determines the rules for social behavior and their principles were translated into norms in various contexts. The Greco-Christian philosophical notion of *agape* encouraging the persistent unconditional universal inclusion of “everyone” in all considerations regardless of circumstance could be considered to lay the basis for the transcending nature of inclusiveness in Stakeholder thinking today.

Ever since businesses were granted limited liability in Britain and France in the nineteenth century, discussions had been ongoing about what society can expect in return, how business affects people’s lives, and about how we can create a better, easier, happier world (Bregman 2016). Adam Smith and Emmanuel Kant were both inspired by the enlightenment movement, which laid the foundation, at least in an abstract way, for thinking on Human Rights. Kant translated the Charity Commandment into a modern-day guideline by emphasizing in his categorical imperative that in any activity all individuals should be considered under the rule that guides that activity. This was later formalized in the creation of the UN Declaration of Human Rights in 1949. According to Kant (1785), the rights of the individual are best honored by adhering to deontological principles, i.e., that the action should be based on the duty to honor universal principles. Kant’s advice to always treat others in relationships as ends and not as means, contrasts with the consequentialist approach of Adam Smith, who advocated the utilitarianist view of achieving the “best” outcome in any social context. Smith designed the market concept as a platform upon which individuals can be effective in meeting their own needs.

They must however be responsible toward others in meeting those needs (Smith 1759). This was based on the optimistic belief that individual rights can be achieved via market mechanisms. To safeguard stakeholder relationships, social legislation was enacted by the Government in the following 150 years during the period between the publication of Adam Smith's *Wealth of Nations* and the Second World War. In this period, legislation supporting the rights of the individual in the market was drawn up, such as maternity leave, working hours, and other similar social legislation. These developments exemplify in an economic or market setting, the ongoing attempts to ensure that all life is honored. This focus on the interests of "others" could be considered to set the stage for the first Stakeholder Relationships between business and society.

Academics studying strategy identified that 70 years ago management decision-making was increasingly influenced by stakeholders. In the 1950s and 1960s, America and Europe experimented with managerial capitalism in which big business worked with the government and unions to offer workers job security and perks. However, after the stagnation of the 1970s, shareholder value took hold, as firms sought to maximize the wealth of their owners and, in theory, maximize efficiency (The Economist 2019, p. 9). Arguably, one of the most prominent articulations of the view that the only responsibility of the corporate executive was to maximize profits for shareholders, derived from the economist Milton Friedman. In an article in the *New York Times* in 1970, Friedman stated that the social responsibility of business is to increase its profits (Friedman 1970). Friedman's view influenced the next 40 years of economics leading to finance-based thinking. This hardened the "business case" against the logic of corporate social, environmental, or other responsibility, thereby diminishing the relevance of any stakeholder groups beyond the needs and interests of the provider of capital to the enterprise – the shareholder (Idowu and Schmidpeter 2017, in O'Riordan 2017, p. ix). According to Remmé (2013), in that time, while some companies showing leadership developed in the direction of stakeholder thinking,

many were primarily inward looking, seeing only those stakeholders who were important for the success of their primary processes. This era has been described as "a period of total ignorance in the free-market capitalist world" ...or perhaps... "part of the nonchalant attitude of the old capitalism" (Idowu and Schmidpeter 2017, in O'Riordan 2017, p. ix).

Over the years however, several developments compelled corporate decision-makers to look beyond that narrow shareholder focus. Examples include a book published in 1972 with the title: *Limits to Growth*. Presenting research, which was commissioned by a think-tank called the "Club of Rome," this book outlined the findings from a study undertaken by the researcher husband-and-wife team Donella and Dennis Meadows. Researching at the Massachusetts Institute of Technology, they built a computer model to track the world's economy and environment thereby identifying the patterns and dynamics of human presence on earth (Meadows et al. 1972). The research forecasted environmental and economic collapse within a century if "business as usual" continued. The book's findings sparked a worldwide debate about the earth's capacity to withstand constant human and economic expansion (O'Riordan 2017, pp. 30–31). Such developments triggered an increasing awareness and concern among many people in society, which were later highlighted by Gro Harlem Brundtland, Chairperson of the UN World Commission on Environment and Development. She noted in a 1987 report titled "Our Common Future," the occurrence of "major unintended changes," which, despite some positive trends with respect to falling infant mortality, increasing life-span, and education opportunities for children among other developments, are influenced by and influence a vastly increased human population (O'Riordan 2017, p. 30). According to Remmé (2013), insights such as these sent a shockwave through Western societies, as they made people aware of pressing concerns regarding the environmental and social impact of business and the scarcity of resources. Ultimately, these developments influenced a broader mindset perspective on the role of business in society.

While scientific findings addressing “the predicament of mankind” relating to climate change have long been criticized by certain groups as doomsday fantasy, new evidence emphasizes the need for society to pay attention to environmental issues. Amplified among other factors by the Trump administration’s denial of global warming, controversy continues to rage amid debates questioning the accuracy of evidence, which indicates the deadly serious impact of climate change. Today, driven by previously unimaginable communication possibilities triggered by new technology, the role of the media and social networking is facilitating a new level of public awareness of environmental and social problems. Among the many persistent, pressing, pertinent problems currently facing society, climate change is sadly however merely one example. Mankind continues to face a long list of what have been termed “wicked” problems (O’Riordan and Hampden-Turner 2021). Wicked problems are comparable to what Aristotle termed “*aporia*.” Some puzzle, impasse, or difficulty (e.g., Camillus 2008). Problems are deemed to be “wicked” when their nature is highly ambiguous with no obvious or reliable solutions (e.g., a solution that works in one timeframe or context might not work in another). They include among others: nutrition and access to water issues, deforestation, lack of food and skills, insecurity, insufficient health care, and pollution.

From the outset, Freeman’s Stakeholder Theory challenged managers to look beyond profits. Today, Professor Freeman continues his unwavering message that the essence of “real” capitalism lies in creating value for all stakeholders and not just shareholders at the expense of other groups and individuals. Stating that “Capitalism is in trouble,” Professor Freeman appeals to us all to “be the generation that makes it better.” His theory in a nutshell is that business must act in the role of a good citizen in the community and society. Moreover, in an interview with *Forbes India*, Freeman emphasizes that businesses should be driven by purpose (Freeman 2018). What better purpose than to invest its resources to address the wicked problems facing mankind?

Capitalism in Crisis: What’s Gone Wrong?

Eugen Schmalenbach, one of the fathers of German business administration, pointed out that because profit maximization is individualistic, it ignores the external effects of business on society. The negative impact of the actions of business decision-makers are then ultimately borne by society (Muscheid 2013). The dominance of shareholder and finance-based thinking in the business world has led to an all-time low in public trust in business and its leaders (e.g., Mallenbaker 2013; May et al. 2007, p. 7; O’Riordan 2017, p. 37; Peters and Roess 2010, p. 8). Moreover, despite the focus on apparent “hard facts” based on numbers and profit maximization in the classic economic models, we possess no plausible concept of how wealth is created.

A key issue with the shareholder value creation rationale is that it is linear. Economists and financial experts focus on endless growth and rarely consider human relationships in their calculations when, as far as wealth and value are concerned, money as the main aim of business is a “sterile” objective. Money can be destructive if it is not created into value. An overemphasis on money has led to a largely unconnected society, in which progress is hindered and ecological and social values are depleted. Freeman points out that it was, ironically, Friedman himself who recognized that the shareholder value rule would work only if businesses obeyed the law and ethical custom. However, many of Friedman’s followers ignored Schmalenbach’s cautioning about the cost to the public of a narrow shareholder focus. The *homo oeconomicus* model developed over time from its original purpose as a mathematically calculable approach for economists into a normative behavioral model for real economic actors (Raworth 2018, p. 117). Under the rule of profit maximization as the main hypothesis, “people” were assumed to equate to “things” and measurement criteria and strategy adapted accordingly. As business and ethics became increasingly disconnected, the quip about business ethics being an oxymoron became recognizable. This approach evidently triggered Elkington’s (1997)

comparison of corporations to cannibals, who, because they are eating with forks, claim to behave in a civilized manner. The inherent flaw and fundamental systemic issues are obvious. While these realizations do not presume that economics or finance are useless or intrinsically corrupt per se, they highlight that money is only created by leveraging and lending out assets. Crucially, however, value is achieved when all parties in an enterprise have more resources between them than they started out with (Hampden-Turner et al. 2019a, pp. 51–61).

Research undertaken by O’Riordan (2017, p. 389) identified both the disconnecting quality of an overemphasis on profit maximization, as well as the converse connecting quality of inclusive prosperity maximization. Based on Drucker’s reasoning that all quantity is ultimately based on quality, “more profit” is a meaningless objective if it is not connected with some rational explanation of what quality it seeks to serve. Nevertheless, the role of people and social instincts, including the relevance of culture, and how values shape human progress are typically ignored in contemporary economics despite evidence of their salience (e.g., Harrison and Huntington 2000). Charles Hampden-Turner refers to this as “the colossal mistake in science,” which studies people using instruments designed for use in the natural sciences (Hampden-Turner 2018). Clearly, if this cause-and-effect logic worked, we could “cause” people to be more productive.

Management decision-making based purely on a rationale of disconnected economic-thinking and the view that the only responsibility of the executive is to maximize profits for shareholders is a false premise that is not sustainable. The rationale for this realization is outlined in the historical development presented above. It is based on the reasoning proposed by philosophers since the beginning of civilization about how to lead a “good life,” achieve “prosperity,” and thereby realize the full development of each being’s natural potential. Instead of fostering a wealth-creating cycle generating surplus value by generously supporting stakeholder groups, including employees, customers, the community, the government, and the environment, shareholder dominance

in management decision-making is destroying not merely wealth but also eradicating creativity and innovation (Hampden-Turner et al. 2019a, pp. 22, 53). People are increasingly beginning to realize that an overemphasis on shareholder interests is harmful to society and the environment (Hampden-Turner et al. 2019a, pp. 28–37).

The overly prolonged belief that a short-term shareholder focus is a reasonable way to invest collective resources is misled. The prime purpose of industry has become reduced to a means to make money for shareholders by exploiting other stakeholders’ interests in the process. The resulting disconnect between business and society has led to social problems arising from gross inequalities. Rather than realizing “utopia” in the sense of advancing human rights and “good citizenship” in line with the reflections of the early Greek philosophers, theologians, and humanists who maintained that we are all united under the same principles to “love our neighbour,” instead, a highly complex web of persistent multiple sustainability challenges has emerged. The “predicaments of mankind” noted previously have been described as “wicked” problems. They are frequently symptoms of other problems, meaning that addressing one typically uncovers more challenges (O’Riordan and Hampden-Turner 2021). The existential dilemmas we face today amplify the urgent need for a new concept of “progress” in management thinking. Addressing the disconnect requires a mindset shift placing the people who actually create the wealth at the center of the business and awarding them accordingly. The related issues were the theme of a book titled: *New Perspectives on Corporate Social Responsibility: Locating the Missing Link*, which focused on the missing link in the business value “chain” (O’Riordan and Zmuda 2015).

Future Directions

In a Ted Talk on 14 June 2013, the Harvard Business School Professor Michael Porter renowned for his theories on economics and business strategy asks why society has not yet satisfactorily addressed the wicked problems it faces

and why have they not yet been solved? In doing so, Porter bridges the terrain linking social and corporate ventures. While admitting that there are undoubtedly many bad actors in business, including examples from the banking, pharmaceuticals, and fast-food industries, among others, Porter reaches the conclusion of what he terms “the awkward reality” that not enough progress is being made by other groups. While some incremental improvement has been realized to date by Government, NGOs, and via Philanthropy, according to Porter, based on the current model, these lack the resources (i.e., money in the form of either Government taxes or philanthropic donations) to achieve the large-scale impact required to address the wicked and increasingly intensifying problems facing mankind. In contrast with those who claim that environmental and social problems are typically *caused* by business, i.e., that *business is the problem*, Porter’s thesis is that because business makes profits by solving problems, *business is the best means to solve social problems*. Moreover, Porter highlights the powerful role of business in society based on the positive impact it can generate on stakeholder well-being by delivering taxes, incomes, and charitable donations, among other benefits (Porter 2013).

Wicked problems call for wicked solutions. Stakeholder Value Creation (SVC) by passionate entrepreneurs is one such solution. However, the premise for realizing inclusive sustainable value outcomes is a change in perceptions about stakeholder relationships and how commercial value is created. The crucial prerequisite for achieving this mindset shift is for decision-makers from the public and private sector to cease making disconnected choices from the perspective of the past profit-maximizing logic. Presupposing that the purpose of business is to make profits is short-sighted. This was explained in an analogy expressed by Dennis Bakke, founder of the international power company AES, who stated in an interview with Robert M. Grant: “Profits are to business as breathing is to life” (Grant and Jordan 2015, p. 23). As Grant and Jordan point out, while breathing is essential to life, it is not the purpose

for living (Grant and Jordan 2015, p. 23). Similarly, profits are essential for the existence of the corporation, but they are not the reason for its existence. Instead, according to Freeman (2018) from an online article with Forbes in India, the purpose of business is usually determined by a passionate entrepreneur chasing a dream to change the world. Executives must create as much value as possible for customers, suppliers, employees, communities, and other stakeholders.

What creates wealth are relationships and mutuality. This fosters equality as a meta value above other values. (Equality in terms of interests and access to opportunities, not equality in outcomes, as the socialists would have it). Based on this rationale, we treat others as equals not for moral reasons but because it elicits the best from them. Concurrently, protecting and promoting a range of stakeholder interests in this way requires a transformed strategic mindset regarding the way value is created by corporations. Instead of struggling against their competitors as if they were their “enemies” in the “battlefield” of the marketplace as is the case in the current shareholder-orientated approach, stakeholders collaborate as value cocreators cooperating via relationships with further stakeholders in other network entities. Via the conscious choice to transition to this innovative, synergic, harmonized logic, consistent, coherent, synchronized possibilities unfold, thereby leading to an ultimate higher yield for the benefit of all.

Stakeholder thinking is aligned with the values of the Greco-Christian philosophical notion of agape. It encourages the unconditional universal inclusion of “everyone” in our consideration in a way which transcends and persists regardless of circumstance. Based on the rationale of its inclusive principles, stakeholder theory undoubtedly holds the potential for a better way forward. Business can benefit from creating wealth when it meets needs at a profit while considering the impact of its actions and the external effects of its corporate strategies. That is how wealth is created, which leads to more wealth for all.

Future developments will require fundamental change in the relationship between business and other stakeholders in society today and how to

manage Stakeholder Relationships. Including the interests of more stakeholders in their choices confronts decision-makers with a challenging task. Finding new ways to address the frequently diverse and sometimes conflicting interests and concerns of a wide range of distinctive, context-specific network of stakeholders, as well as differing levels of involvement with them, is not easy. Freeman (2018) highlights the need today for a mindset shift in the form of a deeper connection and purpose for business. Based on the objective to seek to create mutual value by connecting all the entities that are impacted by the decisions of the organization, Freeman emphasizes how, going forward, every business model must be built on stakeholder principles, which then form the essence of capitalism. A mindset reset, as well as new strategies and measurement methods and criteria are required to achieve this shift. It will necessitate a transition to a circular business model. This theme is addressed in a separate Encyclopedia entry by this author (see ► [“Innovative Business Models”](#)).

While Adam Smith designed the market idea as a platform upon which individuals can be effective in meeting their own needs, he highlighted that they must be responsible toward others in meeting those needs (Smith 1759). If we assume that we are all here to serve some purpose (Aristotle argued that all living beings strive for perfection as a principle purpose), then we require some goal or purpose to direct our activities. If the principal goal of society is well-being, then the only reasonable role for business is to serve the well-being of others. This is how business meets needs and ultimately generates sustainable profits. Optimally organizing the systems and structures in society to ensure long-term prosperity in a way that results in a fair distribution of wealth where people continue to exist in harmony with nature could consequently become the over-arching rationale for business. While being careful not to understate the important role and needs of other stakeholders, business plays a very powerful role in sustainable SVC.

The SVC notion was proposed by O’Riordan (2017) in her book: *Managing Sustainable*

Stakeholder Relationships: Corporate Approaches to Responsible Management, as an umbrella concept, which represents the three interrelated principles of multiple, collaborative, and connected value. SVC is “Multiple” because it is inclusively created by and for many varied parties in a network. It is “Collaborative” because the value is created mutually among and between the various constituents in the network. It is “Connected” in the sense of being “shared” based on the idea that was popularized by M.E. Porter and M.R. Kramer (2011). They defined shared value as “policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the communities in which it operates” (Porter and Kramer 2011, p. 6). Similar to Porter and Kramer’s (2011) interpretation, connected value is created by reconsidering products and markets, reformulating productivity in the value chain, and developing supporting local clusters. It differs significantly from shared value in the sense that it focuses not on an organization-centric profit-maximization aim in the first instance, but rather on creating value driven by purpose via *the stakeholder connections*, i.e., *within but also between* the parties in the network (O’Riordan 2017, pp. 377–416).

Constructed upon the fundamental idea of creating a multiple, collaborative, and connected value proposition within the notion of a circular economy, SVC designates a process for realizing a supply of offerings to clients, customers, and/or the community, ultimately leading to (re-)design via cocreation, and thereby, sustainable added value for a range of constituents. The combined effect of these three principles enables the creation of *augmented broad-ranging stakeholder-orientated value optimization* in place of narrowly focused shareholder-orientated profit maximization. For clarification, by definition, the three principles of SVC are interrelated based on the rationale that they are founded on many of the values of sustainability (Brundtland 1987; Elkington 1997; McDonough and Braungart 2002) (see ► [“Sustainability”](#)).

Summary

Stakeholder Value Creation constitutes the conscious awareness about how wealth is created and how the choices of decision-makers impact others. It strives to address the challenge that shareholders and the financial sector of the economy have become severed from stakeholders within companies who do the actual work and create the wealth we all enjoy. The resulting gross inequalities have led to reduced salaries and wages and other declining rewards for those working on productive tasks and delivering genuine value. Moreover, it has diverted funds from the most important contributors away from sustainable ventures. Consequently, the current system is performing under par on general effectiveness, productivity, and innovation. Economic Man is bereft of purpose and meaning (Hampden-Turner et al. 2019b, p. 19). These issues are socially constructed by the way we have chosen to design the system. The excesses wrought by the traditional perceptions require replacement with a new mindset. SVC advocates a transition to that new way of thinking. It constitutes an increased awareness driven by the entrepreneurial purpose of decision-makers to inclusively create positive impact for all the interest groups who can affect or be affected by the business process of transforming resource inputs (land, labor, capital, enterprise) into outputs (products and services). SVC thus signifies a shift toward sustainable business strategies by highlighting that the value generated by corporations can inclusively create collective well-being with and for multiple stakeholders in society.

Stakeholders

Linda O’Riordan

Centre for Corporate Responsibility (KCC), FOM University of Applied Sciences, Düsseldorf, Germany

Synonyms

Stakeholder management; Stakeholder theory

Definition

Stakeholders are defined as those groups and individuals who can affect or are affected by the achievement of some intended purpose (adapted from Freeman 1984, p. 52). Because stakeholders comprise those with some possible “interest” in some envisioned venture, they are broad ranging both in scope and influence (see, for example, Greenwood 2007; Mitchell et al. 1997, pp. 853–854; O’Riordan and Fairbrass 2008). Stakeholders can accordingly potentially comprise “everybody,” i.e., all those parties possibly impacting and/or impacted by decision-makers aiming to achieve some chosen objective.

In the quest to realize some intended purpose, the **relevant groups** and/or individual stakeholders requiring consideration by decision-makers are **context-specific**, i.e., dependent on

the circumstances of each venture and/or purpose (O’Riordan 2017, p. 61). Potentially deriving from the broader spheres of the political, social, economic, technological realm, among others, the stakeholder spectrum not only spans the entire **macro-environment** affecting some chosen intention, but also the **micro-setting**. Selected examples of stakeholder groups and individuals at the macro-level could, for instance, include Society in general or some specific Community; Government; Policy Makers; Authorities (regulatory and other); the Media; Nongovernmental Organizations; Trade Unions; Business; Industries; among others. While at the micro-level, stakeholder groups could include subgroups or individual actors of the above, such as specific Organizations or Leaders. At the internal Corporate level, many stakeholder subgroups can further emerge, including, for instance: Employees; Customers; Members; Suppliers; Managers; Owners; Shareholders; Creditors; Investors; among others. Each of these groups holds its own distinct types and levels of involvement, and often exhibits diverse and conflicting interests and concerns (O’Riordan 2017, p. 79).

Explication of Related Concepts

Stakeholder Theory is based on the premise that business success is dependent on its ability to make itself relevant for its stakeholders. This broad scope signifies its reach beyond the traditional shareholder view. Instead of the narrow focus on profit maximization in the exclusive interests of shareholders, stakeholder theory advocates a decision-making approach, which inclusively addresses a broad range of stakeholder constituents (including shareholder interests). The significance of stakeholders in realizing whatever chosen purpose is being pursued by decision-makers cannot therefore be overstated. Any number of parties could, as individuals and/or groups, potentially impact an intended venture in two possible ways: either as **friends** and supporters/facilitators of an activity (without whom it would be accomplished less optimally or perhaps not at all); or alternatively, as skeptics with a critical eye

on the venture; and maybe even as **foes** (i.e., possibly blocking or otherwise harming the endeavor). Simply put: the success of any activity stems from its stakeholders (Hampden-Turner et al. 2019, pp. 20–22).

Historical Conceptual Development

Grounded in the age-old wisdom of the maxim encouraging the principle of “honouring” our “neighbour” and echoed in the golden rule advocating treating others as we ourselves would like to be treated, stakeholder theory essentially reminds us to “do unto others as you would have them do to you” (Matthew 22:39). While the “stakeholder” term was apparently first recorded in the 1960s, and although there is some discussion about the development of the concept, the academic literature recognizes the University of Virginia Professor Robert Edward Freeman as the “Father” of Stakeholder Theory (O’Riordan 2017, p. 59). In his book written in the 1980s entitled: “Strategic Management: A Stakeholder Approach” (1984), Freeman broadened the established corporate perspective by focusing on not merely the shareholders, but by additionally identifying the salience of the other key stakeholder groups of a corporation.

The stakeholder view emphasizes the need for decision-makers to be aware that organizations operate as crucial catalysts not in isolation, but as part of several communities. This recognition requires new forms of interaction (e.g., Burchell and Cook 2006, 2008, p. 40; Ethical Corp 2009; Mitchell et al. 1997). For instance, O’Riordan (2017, p. 60) notes that “customer capitalism” (Martin 2010) highlights the relevance for managers to take the other participants inherent in the network within which firms operate, when approaching strategic planning activities (Murray and Vogel 1997, p. 142). Similarly, Carroll and Shabana (2010, p. 101) advocate that business initiatives involving stakeholders in a positive manner can create organizational opportunities thereby ultimately leading to competitive advantage (Greenwood 2007, p. 317; ISO 2011, p. 4). Thus, the stakeholder view emphasizes how managers increasingly need to take the interests of a

broad range of stakeholders in society into account when developing their business strategies (Freeman 1984). This suggests that it makes sense to recognize the needs of the people and to connect the business strategy of the organization with societal needs via offering products and service solutions. In doing so, it is possible that the three rationales proposed by Mitchell et al. (1997, p. 854), including either the *power* of stakeholders to influence the firm, the *legitimacy* of their relationship with the firm, or the *urgency* of their claim on the firm, are likely to influence how managers rank and prioritize stakeholders' interests (O'Riordan 2017, p. 182). Given the aim of management to generate wealth and thereby ensure the firm's long-term survival, organizational decision-makers who choose to ignore the significance of stakeholders do so at their peril (see ► [“Stakeholder Value Creation”](#)).

The impact of corporate decisions on stakeholder groups was recognized by the United Nations (UN) World Commission on Environment and Development (WCED), which proposes a management decision-making logic grounded in stakeholder theory. The principles of Sustainable Development (i.e., the process needed to achieve sustainability) put forward in the Brundtland Report (1987) are based on the premise of meeting the needs of current generations without compromising the ability of future generations to meet their own needs (Brundtland 1987). The expected outcome is the long-term assurance of a global, peaceful, healthy, well-being for mankind via business activities.

The Brundtland definition advocates the connection of economic with social and environmental aims via what was originally termed the “triple bottom line” (TBL) principles (Elkington 1997, p. 2). The TBL advocates a decision-making approach, which takes a triad of interests into regard. They include: Profits (development of a solid economic structure, which facilitates industrialization and reduces unemployment and social issues); People (elimination of poverty, facilitation of human health and education); and Planet (protecting the environment). This leads to synergy and sustainable harmony (see ► [“Triple Bottom Line”](#)).

Further noteworthy developments in this field included an update of the TBL concept by McDonough and Braungart (2002). They advocated the requirement to architect stakeholder interests into products and services already at their conception and design stage. Hence the term “Triple Top Line” (TTL) reflecting stakeholder regard already in the top line (sales), as well as the bottom line (profits) (see ► [“Triple Bottom Line”](#)).

The principles inherent in Sustainability and the TBL/TTL call on corporate decision-makers to reflect upon the impact of their choices on stakeholder groups and individuals in both the ecological and social spheres, among others. This contemporary view has been labeled “Corporate Social Responsibility” (CSR) or “Corporate Responsibility” (CR), which, from the broad and increasing range of possible definitions available, can be understood to include the economic, legal, and ethical expectations placed on organizations by society at some given point in time (Carroll and Buchholtz 2009). In parallel with the increasing critical public and media attention provoked by ongoing corporate “misdeeds,” various authors (e.g., Lindgreen and Swaen 2010; Carroll 1979) note the burgeoning of the academic research on the topic of corporate (social) responsibility. O'Riordan (2017, p. 6) additionally highlights a growth in practitioner concern for responsible business practice, sustainable development, and stakeholder management (see, for example, International Business Leaders Forum (IBLF) 2010; International Organisation for Standardisation (ISO) 2011, p. 4; Organisation for Economic Co-operation and Development (OECD) 2001; World Business Council for Sustainable Development (WBCSD) 2002) (see ► [“Corporate Responsibility”](#)).

Possibly influenced by the rising awareness of the need for sustainable development, triple bottom/top line thinking and corporate responsibility in business decision-making, Laplume et al. (2008) identified a substantial rise in the prominence of stakeholder theory since 1995. Content analysis of the major themes in stakeholder theory undertaken by O'Riordan (2017, pp. 59–60) reveals that the literature clusters around five key

themes. These include its definition and salience, stakeholder actions and responses, firm actions and responses, firm performance, and theory debates (Laplume et al. 2008, p. 1160). Within this context, stakeholder and legitimacy theories (Gray et al. 1995, p. 52; Lindblom 1994; Stark 1994) are concepts which imply that stakeholders have a “stake” in the business (Campbell 2000; Haniffa and Cooke 2005, p. 3; Mitchell et al. 1997; Woodward et al. 2001, p. 357). These both legitimize stakeholder interests and justify that managers invest time and other resources on their stakeholders (O’Riordan 2006).

Today, a salient aspect of responsible management involves preserving with its stakeholders a “licence to operate” or “goodwill to conduct business” (e.g., Ethical Corp 2009; Ulrich and Fluri 1995). In contrast with the isolated shareholder view of the firm, the inclusive stakeholder-orientated perspective emphasizes a network model of stakeholder theory of the firm (Rowley 1997). This recognizes the company as one player within the context of the complicated web of duties and obligations, which all stakeholders hold (see, for example, Crane and Matten 2004, p. 51). The stakeholder perspective thereby “connects” the business with the market and the social system. The theme of *how* business connects with other stakeholders in its network is further developed in two separate entries written by the author in this encyclopedia (see ► “Stakeholder Value Creation” and ► “Innovative Business Models”).

Key Issues

While the traditional view of the corporation suggests that its primary, if not sole responsibility is to its owners, or stockholders, the stakeholder concept proposed by Freeman in 1984 adopts a broader view advocating that an organization’s responsibilities address not only shareholders and owners, but many other constituencies as well, including employees, suppliers, customers, the local community, local, state, and federal governments, environmental groups, and other special interest groups (O’Riordan 2017, p. 5). The stakeholder view also stipulates that shareholders

are best served when a wider range of stakeholder interests are respected. The increased scope of attention inherent in both the inclusive stakeholder concept, as well as the four components of corporate responsibility, trigger new expectations in society regarding the role of organizations. This significantly broadens the scope of management consideration in decision-making.

Existential, persistent, complex issues, arising from adverse man-made and/or natural events taking place at the macro-level (such as climate change, resource depletion, environmental degradation, pollution), as well as the ongoing impact of social and economic developments (such as changes in commodity prices, global economic crises, poverty, access to healthcare, and education issues), cumulatively set the stage for a highly multifaceted and complex operating setting for all decision-makers in the political, social, and economic sphere, among others. The diverse, broad-ranging, interrelated “wicked” issues (Camillus 2008) resulting from these events pose practical management challenges for business decision-makers (O’Riordan and Hampden-Turner 2021). Moreover, they trigger complex questions with respect to who is deemed to be responsible for what, who has a duty to whom, and how to optimally organize and harmonize competing stakeholder interests (O’Riordan 2017, p. 5). Answering these questions trigger tricky debates on matters ranging from responsibility to ethics relating to the overarching interdependency between modern business and society within a capitalist system (May et al. 2007; Welford 1995, p. 114; 2013).

Stakeholder interest in the behavior of firms, and particularly large companies, has been reignited in the past decade or due to numerous reported adverse “events” involving firms from a range of industry sectors, such as banks, telecoms operators, energy companies, and many others (see, for example, The Economist 2013; Mallenbaker 2012; May et al. 2007, p. 7; Peters and Roess 2010; Wagner 2007). According to O’Riordan (2017, p. 7), today the corporate responsibility challenge is no longer about the question of *whether* to behave responsibly, but *how*. Addressing this challenge confronts business decision-makers with a complicated

TBL/TTL balancing act of attempting to unite their company's economic interests with the broader interests of society and the environment.

Responsible Stakeholder Management remains an ambiguous endeavor because identifying how to leverage the resources of the firm to most optimally address the sustainable development challenges noted previously is a complex management task. It is further complicated by the subjective nature of the multidimensional stakeholder expectations involved in this emerging field. Because it is difficult to define, it persistently remains a matter of vivid debate, the overall outcome of which is challenging to measure, and therefore problematic to justify as a strategic approach using conventional financial management or accounting methods (Jonker 2012). Moreover, the management tools for translating notions of sustainable responsible management into everyday business practice inadequately provide feasible management solutions. This is either because they are underdeveloped and lack comprehensiveness, or, in contrast, because they are so overly complicated that management decision-makers view them as incomprehensible (O'Riordan and Zmuda 2015). The resulting lack of transparency for all stakeholders, especially for decision-makers facing the management challenge of identifying an optimal business response, additionally triggers intense debate regarding the rationale (i.e., *why*) integrating responsible solutions into business operations might be considered and justified as a good idea (O'Riordan 2017, p. 7).

Solutions to these challenges require a fundamental reconsideration of the role of business in society. This necessitates a comprehensive review of the entire macro-level system (including political, economic, social, and technological structures and incentives, among others). While this scope clearly reaches beyond the capacity and influence of individual decision-makers within isolated companies, the quest to identify an improved role for business in society prompts the requirement for decision-makers at all levels to critically consider the impact of their actions when designing economic policies and commercial strategies. This expanded reach considerably complicates the task of managing sustainable

stakeholder relationships from a corporate perspective. Stakeholder "engagement," "dialogue," or more generally "relationship management" refers to the approach, system, and processes employed by decision-makers (either as individuals or in an organization) to interact with stakeholders for some intended purpose (see ► ["Stakeholder Relationship Management"](#)).

A review of the literature by O'Riordan (2017, pp. 92–94) proposed eight open issues comprising five management "misunderstandings," or "misconceptions," and three "unsolved challenges" facing decision-makers when attempting to manage sustainable stakeholder relationship. The five misunderstandings/misconceptions from a corporate perspective include:

1. **The Illusion of Separation and the Absurdity of Ignoring the Connections** instead of appreciating the fundamental interdependencies between business and society. Instead, organizational success is clearly dependent upon a constructive relationship with society.
2. **Overlooking the Obvious at Everybody's Peril** instead of recognizing that an alternative approach is required to appropriately address the pressing sustainability issues of our time. Transition to a stakeholder mindset requires new measures and effective mechanisms within the economic, social, and political system as well as at organizational (management) level.
3. **The "Blind" Belief that the Business of Business is Business** instead of realizing that business succeeds best when it serves society's needs with valuable commercial solutions. The business of business is the well-being of society.
4. **The Paradox of Profits and the Limits to Altruism** instead of understanding that over time, a business that is not profitable (either due to an overemphasis on increasing sales or decreasing costs, or, alternatively because of excessive philanthropy) runs the risk of operating as a burden to taxpayers or ceasing to exist. In both cases, the resulting economically unprofitable organizations deliver no value to society.

5. **The False Truth of “Ethical” Business** instead of grasping the voluntary nature of responsible business behavior. Those in search of a moral in business are best advised to read an Aesop’s fable. Because business is amoral it cannot be generally prescribed or judged in the normative moral sense. The interpretation of ethical or moral matters is context-specific. While extremely important as drivers of business values in an organizational context, they are chosen and implemented exclusively on an individual (e.g., leadership) basis. Consequently, they require evaluation at an individual (subjective) level of analysis. Hence, it is difficult to deem or measure business via indicators such as “ethical” or “unethical,” due to the individual nature of ethical conduct (e.g., motivation, as well as the structures, systems, and processes) inherent in the (subjective) notion of responsible profits.

Extrapolated from an extensive review of past scholarship, these aspects arguably reflect the typical prevailing “mindset” with respect to the role of business in society. They pose significant barriers to unleashing the full potential of corporate responsible management strategies in the transition from a shareholder to a stakeholder decision-making perspective (O’Riordan 2017, pp. 92–94). Three key unsolved challenges include:

1. **Rethinking the Logic of Competition:** Rather than on exclusively fighting against one another to accumulate money and materialistic objects for a chosen few, competitive behavior must be reflected. Those who steadfastly believe in the rationale of a shareholder approach must reconsider the sustainability of its wealth-creation logic. To realize the full potential of business in society, the mechanisms of competition must focus on the relationships *between* stakeholders collectively striving together. To optimally unleash the highest potential of each individual group, the wider benefits and costs must be recognized. Distributing the resulting wealth for the
- advantage of a broader range of interests requires new assessment mindset and methods.
2. **The Mystery of Measurement and Management:** If effective measurement is a prerequisite for all management practice, when deciding how to invest the firm’s resources in a sustainable way from a broadened TBL/TTL perspective, what precisely counts as value, who decides, and how is this measured?
3. **Perfection is the Child of Time:** Addressing the above-noted issues will require transformation to a more sustainable future. Such fundamental long-term transition in the traditional industrial capitalist system includes a broadening of the time horizon perspective in policy and business planning. This involves essential changes in the current system, mechanisms, and methods.

Crucially, corporate approaches based on a stakeholder perspective are complicated because they represent value judgments. This involves the proactive (subjective) choice to focus management decisions (both of an internal and external dimension) toward value creation. This signifies a new approach, which clearly goes beyond mere compliance with existing legal requirements. Unsurprisingly however, possibly due to inadequate common agreement regarding the misconceptions and challenges presented above, as well as a lack of consensus on how the perceived value generated by business in society is created, measured, and reported, the topics of business accountability and responsibility continue to remain elusive notions and contested issues for business managers and their stakeholders (see, for example, Acutt et al. 2004, p. 302; Carroll 1999; Crane and Matten 2010, p. 224; Ferrell et al. 2010; O’Riordan and Fairbrass 2008, p. 746). Nevertheless, while stakeholder relationship management is not a new concept, it is widely recognized in academia and increasingly by business as vital to the organization’s success. According to AA1000 (2015, pp. 4 and 6), this is in part due to the principle of including the interests, involvement, and active participation of stakeholders in strategic business choices. The aim being to identify,

develop, and realize accountable, sustainable, strategic TBL/TTL value creation (O’Riordan 2017, p. 79). For further details please refer to the related entry by this author (see ► “Stakeholder Value Creation”).

Future Directions

The principle of inclusivity, which encourages the practice of integrating regard for the interests and participation of stakeholders in decision-making, assumes that there is a role for business in social and environmental problems. The question is: what is that role? Answering it requires reflection on the way the key issues noted in the previous section have been approached in the past so that we can learn from the evidence to navigate a better path going forward. The *noblesse oblige* rationale reasons that the status and power of organizations signify an obligation or moral duty of generous behavior toward others. Because an organization has the competence to offer solutions, it has a responsibility to act. By highlighting the salience of a broader range of stakeholders beyond the traditional shareholder view, Freeman (1984), and later Freeman et al. (2007), and again Freeman et al. (2010) proposed how management could address the interests of a wider and more diverse spectrum of interest groups than merely the owners of the firm.

Freeman’s rationale emerged from the realization that an overemphasis on shareholder dominance is harmful to society and the environment. In their recent book, Hampden-Turner et al. (2019, p. 37) suggest that the threat posed by shareholders to public companies is analogous to cancer’s threat to the human body. Cancerous in the sense that, if any one element in a system is expanded unilaterally, it will first unbalance, then destroy it. The short-term, profit-maximization objective inherent in the shareholder approach is fatal because quick, riskless money-making is a fraud. The point is *not* that shareholders should receive less. However, it is crucial to appreciate that shareholders will only add value if they are *not placed first*

when *it is the stakeholders who are actually doing the work*. Moreover, PROFITS are the CONSEQUENCE of some intended PURPOSE; in that order, profits are not the purpose in the first instance (Hampden-Turner et al. 2019, pp. 28–37).

Awareness of the need to restore the equilibrium of the whole is beginning to dawn on decision-makers. The stakeholder perspective presented by Freeman with its emphasis on a collectively inclusive interpretation of the well-being of society is increasingly replacing the traditional shareholder dominance. Crucially, this development is likely to be essential if the planet is to survive the current effects of climate change and global warming. Simply put, Sustainability requires the efforts of all stakeholders working together. Gradually, the evolution of capitalism is reaching a new stage. Going forward, the best kind of capitalism will draw on the commitments of all those with a stake in the venture. Stakeholder Capitalism is overtaking Shareholder Capitalism. Moreover, it must do so in order to address the “wicked” sustainability challenges facing mankind (Hampden-Turner et al. (2019, pp. 36–37).

It is simply absurd to claim that employees, suppliers, customers, and the environment are mere ‘agents’ for shareholders, that someone who has owned shares for ten minutes ‘owns’ the work of a 20-year employee or 40-year supplier, or cares about the planet. (Hampden-Turner et al. 2019, p. 29)

Solving sustainability challenges will require the cooperation of stakeholders who must be allowed to own what they have helped to create.

Wealth creation and a saved planet belong to all of us and depend on all of us giving what we can. (Hampden-Turner et al. 2019, p. 29)

Relationships among stakeholders are the keys to wealth creation. Most wealth is created however not so much by specific persons or groups, but by the quality of the relationships among these. Companies grow where these are in harmony (Hampden-Turner et al. 2019, p. 31). Accordingly, rather than competing with those we encounter day by day, we need to cooperate

with them to forge win-win solutions. This progresses the organizational purpose from a focus on efficiently “doing things better” to effectively “doing better things.” Inspiring all stakeholders to strive together to “make a difference” is signified in the original Latin meaning of the word competition, which focuses on striving together (as in sports, based on rules to which both parties agree). Via this approach, sustained responsible profits are enabled by means of knowledge as a key connecting mechanism (O’Riordan 2017, pp. 387–388). This stakeholder theme is further developed in a separate entry written by the author in this encyclopedia (see ► “Stakeholder Value Creation”).

Summary

Stakeholders comprise all individuals, groups, or constituents with some possible “interest” in a particular endeavor. Essentially, business comprises the interactions of stakeholder groups creating value for other stakeholder groups. Because stakeholder groups are broad ranging both in scope and influence, they can comprise all those parties who could potentially impact and/or be impacted by decision-makers aiming to achieve some (consciously) chosen objective. While business decision-makers are thus wise to consider their stakeholder’s interests, nevertheless, addressing them has always been tricky. Perceptions of what constitutes the “fair” management of different groups are subjective in nature and fundamentally depend on the context-specific circumstances of each venture, as well as the mindset values intrinsically underlying its purpose. Going forward, business decision-makers will gradually begin to more purposefully recognize that sustainable superior profits essentially derive from satisfactorily fulfilling the expectations of key stakeholder groups, such as customers, employees, and suppliers. Thus, awareness will grow that the conventional exclusive shareholder-orientated business logic of achieving profits at the expense of others, leading to “tragedy of the commons” outcomes, depletes not merely profits in the medium to long term but

the overall collective value. Because diverse stakeholder groups will increasingly expect greater equilibrium of return in stakeholder relationships, achieving sustainable profits will hinge on the how equitably decision-makers choose to treat those groups. Healthy stakeholder relationships shaped by win-win logic unleash a flow of collective value. The profitability of others thus sustains one’s own superior profit performance and long-term economic progress is achieved in the collective interest and the well-being of society.

Standards for the Assurance of CSR Information

Natalia Vaz-Ogando
Department of Finance and Accounting,
University of Vigo, Vigo, Spain

Synonyms

Assurance normalization; Assurance norms;
Assurance standardization; Assurance standards

Description

Standards for the assurance of CSR information arise as an initiative of different standardizing bodies to establish guidelines to be followed by professionals in the assurance process. Its objective is to increase rigor in the practice of this service and thereby improve the credibility of the information.

Noteworthy from an international perspective is the ISAE3000, issued by the IAASB (accounting nature organization) for the assurance of any type of nonfinancial information, and the AA1000AS, issued by AccountAbility

Standards for the Assurance of CSR Information,

(organization focused on sustainability) for the assurance of CSR information specifically. The use of these standards is widely accepted, and they encourage the development of other national standards. Both of them develop a methodology that guarantees a systematic assurance process through different approaches deriving from their distinct nature and scope. The ISAE3000 establishes more formal ethical requirements and control systems, while the AA1000AS emphasizes commitment with stakeholders and compliance with fundamental CSR information principles. Notwithstanding, far from making these norms competitive, these differences make them complementary and thereby offer a more complete perspective for the development of the assurance, facing the demands imposed by the particularities of sustainability information.

Introduction

The assurance of sustainability reports has gained strength in the agendas of various standardizing bodies, both internationally and at the level of each country (O'Dwyer et al. 2011). The need to give credibility to these documents has expedited the development of different assurance frameworks (FEE 2006; Iansen-Rogers and Oelschlaegel 2005; Kolk and Perego 2010).

An analysis of reports taken from the Global Reporting Initiative (GRI) database, an extensive repository of sustainability reports, shows an increasing trend in standardized assurance processes. As shown in Fig. 1, assurance reports with the declared use of a standard guiding the service rose from 64% in 2013 to 75% in 2017.

Two standardization bodies are noteworthy at the international level: AccountAbility, a nonprofit organization aimed at standardization, research, and advice on sustainability matters that issues the AA1000 Assurance Standard (AA1000AS), and the International Auditing and Assurance Standards Board (IAASB), a committee of the International Federation of Accountants (IFAC) issuing audit, assurance, and other related norms, which is responsible for the publication of the International Standard on Assurance Engagements 3000 (ISAE3000). Both are the most widely and increasingly used guides leading the external assurance services for sustainability reports (CorporateRegister.com 2013; Jones III and Jonas 2011; KPMG 2008; Manetti and Becatti 2009; Manurung and Basuki 2010). As shown in Fig. 2, among the assurance reports registered in the GRI database with declared use of standards, 84% referred to international standards in 2012. This proportion increased gradually to 92% in 2017.

Although both international standards are widely accepted, there seems to be a greater willingness to use the ISAE3000 against the

AA1000AS. A slight tendency to use both standards together is also reflected (Fig. 3). The predominance of the ISAE3000 could be owed to factors such as international acknowledgment of its issuing organization as a standard-setting body for the accounting profession and the weight of the Big 4 in the assurance market (see ► [“Assurance Market”](#)).

The importance of international standards is reflected not only in their use but also in the influence they exert on the development of other national standards in different countries (KPMG 2013; Manetti and Becatti 2009). As an example,

Table 1 collects some of the national standards currently used according to GRI registers and identifies, wherever applicable, the international standards on which they are based. Thus, among the European standards are the Generally Accepted Assurance Principles for the Audit or Review of Reports on Sustainability Issues (IDW AsS 821) emitted by the Institute of Public Auditors (IDW) in Germany; the Action Guide 21 issued in Spain by the Institute of Chartered Accountants of Spain (ICJCE); the standard 3410 N Assurance Engagements with respect to Sustainability Reports, issued by the Royal Dutch

Standards for the Assurance of CSR Information, Table 1 National assurance standards

Source: Self-elaborated

Institute of Chartered Accountants (Royal NIVRA) in the Netherlands; the RevR6 Assurance of sustainability reports issued by the Institute of the Accountancy Profession (FAR) in Sweden; and the NAS 950 formulated by the Fiduciary Room in Switzerland. Likewise, in France, the Ministry of Justice published the Order of 13 May 2013 that determines the modalities under which the independent third-party body conducts its mission (NOR: JUSC1222116A) and regulates the assurance process of social and environmental information established in its Commercial Code.

In America, initiatives are developed in countries like Argentina, where the Argentine Federation of Professional Councils of Economic Sciences (FACPCE) launches the Technical Resolution No. 35, Adoption of International Standards of Assurances Engagements and Related Services; Brazil, with the issuance of the NBC TO 3000 by the Federal Accounting Council (CFC); and the United States, where the American Institute of CPAs (AICPA) formulates the standard AT Section 101, Attest Engagements.

In Asia, the contribution of the Japanese Association of Assurance Organizations for

Sustainability (J-SUS) that publishes the practical guide for the assurance of sustainability information is worthy of attention. In addition, the Institute of Chartered Accountants of Sri Lanka (CA Sri Lanka) issues the Sri Lanka Standard on Assurance Engagements 3000: Assurance Engagements Other than Audits or Reviews of Historical Financial Information (SLSAE3000). Likewise in Oceania, the Auditing and Assurance Standards Board (AUASB) of Australia launches the ASAE3000: Assurance Engagements Other than Audits or Reviews of Historical Financial Information.

Interestingly, these mostly generic standards refer to any assurance service other than financial reporting. Furthermore the influence of international standards on the initiatives of the different countries, mainly the ISAE3000, highlights. To a large extent, this influence can be explained by the accounting nature of most national issuing agencies.

Most of the initiatives developed in different countries maintain coherence or are adaptations of international standards, thus enhancing the importance of the latter. ISAE3000 and AA1000AS are both present, either directly or indirectly, in most

assurance processes. Below they are discussed at length.

International Standards: AA1000AS and ISAE3000

The AA1000AS is part of the framework known as the AA1000 series (see ► [“AA1000 Series of Standards, The”](#)), first published in 1999 by AccountAbility. In 2003, this organization issued a revised version with a specific assurance standard, the first worldwide standard for the assurance of sustainability reports. Its current version, published in 2008, is the result of a review process with a multi-stakeholder orientation, based on experience and continuous learning (AccountAbility 2008a). This standard addresses any professional that provides external assurance services for sustainability reports. In addition to establishing the guidelines for professionals to implement the assurance process, it is considered a tool for companies to assess the degree of adherence to the principles established by AccountAbility in terms of management, performance, and communication of sustainability issues (AccountAbility 2008a). These basic principles (AA1000APS) are materiality, completeness, and responsibility, under the fundamental premise of the involvement of stakeholders (AccountAbility 2008b). A guide for assurance providers complements the standard, to achieve a deeper understanding of the key aspects that allow it to be correctly applied (AccountAbility 2008c).

The contents presented in this document follow in the logical sequence of an assurance process. After an introduction explaining aspects like its evolution, development, or scope, the standard is structured in five parts. The first part establishes the main purpose or aim, which is to institute the requirements for the assurance providers to evaluate the information and conclude on adherence to the fundamental principles as well as quality. The next part proposes indications concerning the use of the standard. It distinguishes between two types of engagements, depending on whether the assessment only evaluates adherence to the

principles (type 1) or it also evaluates the reliability of certain contained information in terms of completeness and precision (type 2). Two levels of assurance, high and moderate, are also considered. The first one provides the highest level of confidence at a lower risk of providing an erroneous conclusion. Given the amount and nature of the analyzed information, the norm contemplates the possibility of establishing high levels for some issues and moderate levels for others. Likewise, it establishes the need to refer to the standard, when applied in the process, including the rest of the AA1000 framework documents and other related standards, guidelines, and legal requirements whenever required. The third section addresses the conditions for accepting an assurance engagement, in terms of the determination of the scope and due checks and agreements to be reached by the professional with the contracting company before the implementation; the independence and impartiality requirements of professionals; the necessary skills; the professional care; and the contract terms. Let us point out that the commitment to stakeholders is explicitly mentioned among the necessary competencies. The fourth section establishes the guidelines for implementing the process. It distinguishes three more phases after the acceptance: planning, performing, and reporting. In the planning phase, decisions are made concerning tasks or the use of resources; engagement performing is the one in which the necessary and sufficient evidence is collected so that the assessor can form an opinion on the analyzed information and establish the need for proper documentation; and the reporting task must take some minimum contents into account along with the chance to prepare a separate report for company management. Additionally, the standard includes a definitions section that clarifies the key concepts. The assurance engagement is defined as the one in which

...an assurance provider evaluates and expresses a conclusion on an organization's public disclosure about its performance as well as underlying systems, data and processes against suitable criteria and standards in order to increase the credibility of the information for the intended audience. (AccountAbility 2008a, p. 23)

On the other hand, the ISAE3000 was issued for the first time by the IAASB in 2004 to lead any engagement other than the audit or historical review of financial information, including the external assurance of sustainability reports. The current version was published in 2013, and despite focusing its interest on the standardization of the accounting profession, the use of the ISAE3000 was not limited to this kind of professionals.

This standard is structured in five sections: introduction, objectives, definitions, requirements, and application and other explanatory materials. The introduction considers aspects such as scope and the relationship with other standards. The ISAE3000 establishes that professionals who implement the assurance engagement should be governed by parts A and B of the Code of Ethics emitted by the International Ethics Standards Board for Accountants (IESBA), which includes the requirements of professional ethics that auditors must comply with in the service of the public interest, and the International Standard on Quality Control 1 (ISQC 1), issued by the IAASB, which determines the responsibilities and requirements regarding the quality control systems of the assurance services. The second section describes the objectives of the assessor accepting an assurance engagement, which should be aimed at evaluating and verifying that the analyzed information contains no errors, and it must express and communicate a written conclusion on the obtained results. The definitions section aims to facilitate the understanding of the most relevant terms. Thus, assurance engagement is defined as that in which:

... a practitioner aims to obtain sufficient appropriate evidence in order to express a conclusion designed to enhance the degree of confidence of the intended users other than the responsible party about the subject matter information (that is, the outcome of the measurement or evaluation of an underlying subject matter against criteria). (IAASB 2013, paragraph 12 (a))

Depending on the assumed risk, the engagements may be considered reasonable or limited, similar to the high and moderate levels of the AA1000AS. The norm refers to the assurance of a large number

of possible subjects, so it would be illogical to set a certain level of assurance a priori. The fourth section establishes the requirements to carry out the process. It begins by referring to the need to comply with each of the requirements of the standard and other specific rules, if necessary, emphasizing the importance of ethical standards, quality control, or any other legal provisions. It references aspects like the fact that the assurers should act with professional skepticism (an attitude that implies an inquisitive and critical mentality on the evidence) and apply their professional judgment to make decisions throughout the process, and it indicates the required assurance skills and techniques to be used. The rest of the requirements establish the guidelines for the acceptance, planning, performance, and preparation of the assurance report. The acceptance and continuation of an engagement must consider the necessary preconditions, scope limitations, and terms of agreement between the supplier and the contracting firm. Likewise, it must take into account the characteristics and responsibilities of the partners and the teams to ensure an adequate quality control of the process. Regarding work planning, the standard considers aspects such as scope, materiality (relative importance), and adequate understanding of the subject based on the assurance level. The norm establishes the way to perform the service and obtain evidences, considering the risk and the treatment of the different assurance levels, the actions regarding the work of experts and other professionals, as well as the inclusion of any required written representations. It also defines procedures for significant subsequent events and the existence of other related information and makes reference to the need for evaluating the information with respect to applicable criteria. The requirements for the preparation of the assurance report focus on its basic contents and the elaboration and types of possible conclusions. Finally, it establishes the need for the entire process to be properly documented. The standard ends with an application section and other explanatory material that clarifies and specifies concerns related to each of the previous sections.

Standards for the Assurance of CSR Information, Table 2 International standard comparative

		AA1000AS (AccountAbility)	ISAE3000 (IAASB)
Similarities	Assurance engagement purpose	Increased credibility of the users	Increased credibility of the users
	Assurance levels	Depending on the risk: high or moderate	Depending on the risk: reasonable or limited
	Process phases	Acceptance, planning, performance, reporting	Acceptance, planning, performance, reporting
Differences	Issuer's approach	Sustainability	Accounting
	Assured document	Sustainability reports	Any nonfinancial report
	Professional's objective	To assure that materiality, completeness, and responsibility principles (type 1) and information reliability (type 2) are met	To assure that the information is free from material errors
	Other related regulations	AA1000APS	Code of ethics and ISQC 1, both from IFAC standard setters

Source: Self-elaborated

After its brief description, Table 2 summarizes the similarities and differences between key aspects of the two standards. It can be said that the common objective of the AA1000AS and the ISAE3000 is to ensure greater rigor in the practice of assurance, improve the credibility of the communication exercise, and provide criteria to judge the degree of confidence in such assurance services (Owen and O'Dwyer 2004). Both standards are issued by international organizations and can be used by any kind of professional. This favors greater geographic diffusion and acceptance. Furthermore, they establish different assurance levels, depending on the risk assumed and the degree of added confidence and define a four-stage process that considers acceptance, planning, performance, and reporting.

However, while the IAASB is an accounting organization, AccountAbility is oriented toward sustainability. This causes differences in terms of the scope and the contents of their respective standards (Manetti and Toccafondi 2012). In fact, the AA1000AS focuses exclusively on the assurance of CSR information, while the ISAE3000 is applicable to the assurance of any type of nonfinancial information. Regarding the assurors' objective, according to the AA1000AS, it must be to check the compliance with the

materiality, completeness, and responsibility principles included in the AA1000APS standard, based on stakeholders' interests (type 1), and verify the reliability of certain information considered material when it proceeds (type 2). Nevertheless, the ISAE3000 asserts that the professional's main objective is to verify that the information is free from material errors, expresses a conclusion concerning the evaluated information, and communicates whatever the standard requires.

In sum, developed standards and global frameworks have important implications for assurance professionals. They allow for a more structured and credible service (Crawford 2011). However, the different perspectives emanating from each of them may justify that, in practice, significant differences are observed in the assurance reports with respect to definitions, methodology and contents (Adams and Evans 2004; Deegan et al. 2006a, b; Hasan et al. 2003; Jones et al. 2014; Perego 2009). Risk minimization, robustness and rigor fundamentally characterize ISAE3000, while greater orientation toward the stakeholders (Edgley et al. 2010) characterizes the AA1000AS. So, two essential aspects of this generic comparison should be highlighted to achieve a better understanding of the assurance process: the

existing structural similarities and the differences in approach.

A Similar Process with Two Different Approaches

As indicated, both AA1000AS and ISAE3000 refer to the need to implement a systematic process that includes acceptance, planning, performance, and reporting stages.

The establishment of the assurance level is an essential element in the acceptance phase that determines the type of service to be offered. The assurance level of sustainability reports must be clearly stated to avoid a gap in expectations between the company, the service provider, and even the information users (Manetti and Becatti 2009). In this case, limited or moderate levels are the most common because the sustainability reports integrate quantitative and qualitative data deriving from processes difficult to formalize due to aspects such as stakeholder participation or the balance of their needs (Ballou et al. 2006; Manetti and Becatti 2009). In addition to the scope considerations, ISAE3000 and the AA1000AS agree that the assurance providers must perform a series of checks before accepting a request to confirm they comply with the requirements and standards under which they are accepted and that the reporting company acts in good faith. First of all, suppliers must verify that the purpose of the engagement is appropriate and that adequate criteria for evaluating the information are available to the public. These criteria must be relevant, exhaustive, reliable, neutral, and comprehensive. According to the AA1000AS, the criteria could be specifically developed, although those already established and found in legal requirements, guidelines, and standards are preferable. Likewise, before accepting an engagement, assurers must ensure they have the necessary ethical capacities and requirements to perform the service. In this sense, both standards establish minimum levels of quality, experience, and knowledge to perform the assurance with due diligence. Assuror independence is a fundamental requirement for both

standards. It should be noted that ISAE3000 emphasizes ethical and quality requirements and the technical capabilities of the professionals, while the AA1000AS also expresses, in a concrete way, the need for professionals with demonstrable skills in CSR information and a professional relationship with stakeholders.

Regarding planning, both norms agree on the importance of this stage in which the assurance strategy is developed. It is considered a reiterative phase that must be present throughout the process, taking into account aspects such as the scope of the engagement, the expected timing, the required resources, and the intended users. On the other hand, concerning the performance of the assurance, both standards establish the guidelines for obtaining evidence needed to form an opinion, including examples of tests to be implemented. While ISAE3000 is more detailed in terms of how to deal with certain aspects, such as the treatment of materiality or the work of external professionals, the AA1000 devotes a specific section to evaluating information on sustainability performance.

The result of the assurance process is the issuance of a report clearly reflecting the assuror's opinions and recommendations. This is the only visible part for users to decide on the credibility of the information. In this sense, the ISAE3000 gives a more specific definition of the different types of possible opinions and the circumstances under which they should be applied. Likewise, both standards establish minimum contents of the assurance report. Table 3 summarizes them and shows numerous similarities and some differences that reflect the different standard approaches. Both take into account fundamental information such as the addressees of the assurance report, the responsibility of the organization and the provider, the specification of the standards used, the description of the assured information and the work performed, the indication of encountered limitations, the criteria applied, the level of assurance, the results and conclusions obtained, the declaration of independence, and the assuror's competences and identification. However, while the AA1000AS includes observations and recommendations among its fundamental elements, the

Standards for the Assurance of CSR Information, Table 3 Contents of the assurance report according to international standards

Contents	AA1000AS	ISAE3000
Title of the report		x
Assurance report addressees	x	x
Responsibility of the organization and the assurance provider	x	x
Assurance standards	x	x
Description of scope and type of assurance	x	x
Description of assured information	x	x
Description of the work performed	x	x
Limitations	x	x
Applied criteria	x	x
Assurance level	x	x
Results and conclusions	x	x
Observations and/or recommendations	x	
Declaration of assurer's independence	x	x
Declaration of the assessor's competences	x	x
Quality control requirements		x
Provider's name	x	x
Date and place	x	x

Source: Self-elaborated

ISAE3000 places greater emphasis on the requirements of quality control.

The comparative between the two norms of major implementation at an international level highlights that a very clear sequence in the process of assurance is defined in both cases. However, the different nature of the issuing organizations has a significant influence on the approach of these standards. While the ISAE3000 establishes more formal ethical requirements and control systems and relies on existing regulations for the audit profession, the AA1000AS is a more specific standard, emphasizing the commitment with stakeholders and the compliance with fundamental principles of CSR information. In addition, the AA1000AS highlights the company's

management systems and the strengths and weaknesses in the content of the sustainability reports, while the ISAE3000 focuses on documenting perceived challenges and limitations in the information process (Crawford 2011; Iansen-Rogers and Oelschlaegel 2005). As a consequence, the result obtained using one or the other standard may be different (Iansen-Rogers and Oelschlaegel 2005). Given this situation, some authors advocate the regularization and issuance of a common standard for all assurance providers in an attempt to minimize the deficiencies in the process (Smith et al. 2011; Utama 2011). Others consider that the ISAE3000 and the AA1000AS should be contemplated as being complementary to one another, not substitutes. Combining them will provide better results in the assurance process (Borkowski et al. 2011; Deegan et al. 2006b; Iansen-Rogers and Oelschlaegel 2005; Jones III and Jonas 2011; Marx and van Dyk 2011).

Summary

The standardizing initiatives are an important driver for the development of external assurance of sustainability reports. In this regard, international standards ISAE3000 and AA1000AS (issued by the IAASB and AccountAbility, respectively) are worth mentioning. Both standards intend to guide the work performed by assurance professionals to determine the degree of confidence users can place in the information. The acceptance of these standards is evident, both for their use by the assurers and their impact on the development of national standards in different countries.

Both standards consider that the purpose of assurance is to increase information credibility. This leads them to considering many concerns in a similar way. However, the different nature of their issuing organisms and each of their scopes also cause differences in their approach. As shown in Fig. 4, the existence of a structured process starting from a common element provides the system to perform the service in a coherent and professional manner. Given its emphasis on ethical and quality requirements,

Standards for the Assurance of CSR Information,

Fig. 4 Combination of international standards: ISAE3000 and AA1000AS. (Source: Self-elaborated)

Source: Self-elaborated

the ISAE3000 may provide the necessary formalism to increase the confidence from the point of view of the process. The AA1000AS can promote greater confidence in the fulfillment of assurance sustainability report objectives because it emphasizes the importance of the stakeholders more explicitly, this being the key element of the CSR and its communication.

The joint consideration of these two standards may provide a holistic approach to the process with technical aspects close to those of the traditional financial audit and the necessary adaptations that the particular characteristics of sustainability information require.

[Stockholm Convention on Persistent Organic Pollutants](#)

Definition

In the course of the twentieth century, the use of chemicals increased substantially. This development led to a growing awareness of the negative effects some of these chemicals had on the environment. Global consensus was reached to manage these chemicals with an international treaty. The Stockholm Convention on Persistent Organic Pollutants (POPs) is an international agreement aiming to safeguard human health and the environment. POPs are chemicals with special characteristics: they do not degrade easily, remain in the environment for a long time, and therefore can be transported over long distances. They are bioaccumulating; this means that they reach high concentrations in the fatty tissue of organisms. Furthermore they are poisonous for humans and the environment.

The Convention holds provisions for the elimination of these substances. If it is not possible to eliminate them, the Convention holds provisions for their reduction. Some of the POPs are substances which are not produced intentionally but form as by-products. The Convention also includes provisions for these unintentionally produced substances. Negotiations for the Stockholm Convention on POPs were accomplished in 2001, and the Convention entered into force in 2004. At the beginning, the Convention listed 12 persistent organic pollutants (the “dirty dozen”) including substances like DDT or dioxins. Article 8 of the Convention also provides details on how to add new substances. The full text of the Convention can be found on the website of the Stockholm Convention (UNEP 2017a). Up to now the list of substances regulated by the Stockholm Convention has been enlarged several times.

Development of the Convention

Since the 1960s, there has been a growing public unease about the negative consequences of toxic chemicals on human health and the environment. One substance of increasing concern was the pesticide DDT. It used to be one of the most commonly applied insecticides in

agriculture worldwide. It was (and is) also used as an agent to kill mosquitoes which can transmit malaria. This is referred to as vector control because mosquitoes are the vectors transmitting malaria and new infections are avoided by killing insects transmitting the disease. In the 1970s and 1980s, the agricultural use of DDT was banned in many countries, e.g., the United States and Europe, as a consequence of its negative effects on the wildlife (Mirmigkou and de Boer 2015).

Chemical management was one of the major topics in the 1992 United Nations Conference on Environment and Development. In Chapter 19 of the Agenda 21 document on environmentally effective management of toxic chemicals, it says that states commit themselves to reducing the exposure to toxic substances as far as possible. Also states endeavor to substitute these substances with less toxic chemicals to finally come to a phase out of substances that represent unacceptable risks to human health and the environment (Selin 2010). This way the UN Conference on Environment and Development provided an impulse for a global management of POPs (Vanden Bilcke 2003).

At the time several international agreements on hazardous substances were set up which differ in focus (see Fig. 1). Two important global agreements were the Basel Convention (1989) on the movement of hazardous waste between countries and the Rotterdam Convention (1998) on international trade of hazardous chemicals. Similar to the Stockholm Convention (2001), these global treaties aimed at protecting human health and the environment from hazardous chemicals including hazardous waste.

A regional multilateral agreement was the Protocol on POPs to the Convention on Long-Range Transboundary Air Pollution, abbreviated as the CLRTAP Protocol on POPs (1998). This international agreement was about reducing the transport of certain toxic and persistent substances across borders and the control or reduction of their discharge. This agreement could also be seen as one of the starting points of the development of the Stockholm Convention (Kohler and Ashton 2011). In 1997 the Governing

Stockholm Convention

(2001), Fig. 1 Important international treaties on the management of hazardous chemicals. Solid lines represent global agreements, and dashed lines represent regional treaties. The agreements differ with regard to the life cycle stage of the chemicals. All agreements aim at protecting human health and the environment

Stockholm Convention

(2001), Fig. 2 Structure of the Stockholm Convention containing provisions regarding elimination, restriction, and minimization of substances. The Annexes of the Convention contain lists of substances and screening criteria

Council of the United Nations released the decision to initiate a global treaty on POPs (Vanden Bilcke 2003). About 2.5 years later, the negotiations were completed successfully. The Stockholm Convention was signed in 2001 and came into force in 2004 (Richter et al. 2001). More than 180 countries signed the Convention; the current number can be found on the website of the Stockholm Convention.

Convention Structure

The text of the Stockholm Convention contains regulations pertaining to different stages of the

life cycle of POPs. The life cycle stages that were considered are formation, production and use, international trade, and disposal of waste and management of stockpiles (Richter et al. 2001; UNEP 2017a). The objective of the Convention (protection of human health and the environment) is given in Article 1. The structures of the Articles and Appendices reflect the different fields of action: reducing environmental concentrations, listing of POPs, information exchange, and support (see Fig. 2). Articles 3 and 4 regulate the reduction and elimination of POPs pesticides and industrial chemicals. Signing parties need to prohibit these chemicals and or take legal or administrative measures. Article 5 addresses

the minimization or, if possible, elimination of unintentional POPs like dioxins. Article 6 regulates the disposal of waste and the management of stockpiles. Articles 8 and 22 describe the procedure of adding new substances to the list. Substances of which production and use are to be eliminated are listed in Annex A of the Convention. The pesticide Lindane is an example of a chemical listed in Annex A. Substances to be restricted in use are given in Annex B (e.g., DDT, which can be used under a specific exemption for vector control to fight malaria). Annex C lists unintentional POPs like dioxins or hexachlorobenzene (Kohler and Ashton 2011; Vanden Bilcke 2003). Signatory parties should minimize or if possible eliminate the formation of substances like dioxins or hexachlorobenzene. Annex D of the Convention contains screening criteria which help to identify substances that should be added to the Stockholm Convention. Integrating the Precautionary Principle into the text of the Stockholm Convention was a matter of discussion before it was agreed upon (Maguire and Ellis 2003). The Precautionary Principle means that absence of scientific certainty should not be a reason for not taking action (see entry ► [“Precautionary Principle”](#)). Finally the Precautionary Principle was referred to in several parts of the Convention text. It is mentioned, for example, in the Preamble, in the objective, and in the provisions for designating new additional POPs to the Convention (Article 8). Hereby, e.g., the addition of new candidate POPs can be suggested even if full scientific certainty about negative effects of the chemicals is currently not available.

Stockholm Convention POPs

The POPs regulated under the Stockholm Convention have four main characteristics:

- These chemicals are toxic to humans and the environment.
- They do not degrade easily and prevail in the environment for a long time after release.

- They can be transported over long distances. Consequently POPs are found in remote locations where they have not been produced or applied before, for example, in Polar Regions (Li and MacDonald 2005).
- POPs bioaccumulate. This means that the substances accumulate in the fatty tissue of organisms. Concentrations of POPs can rise exponentially along the food chain with the highest concentrations found in top predators such as polar bear or bald eagle. The latter phenomenon of increasing concentrations at higher positions in the food chain is called biomagnification.

These specific characteristics of POPs make a sustainable management of these chemicals particularly challenging. Due to their persistence and toxicity, they can cause environmental problems far from the original location of use and long after release. The Stockholm Convention addresses a variety of substances. POPs can be grouped into three main categories, namely, pesticides like DDT or Lindane, industrial chemicals like polychlorinated biphenyls (PCB), and so-called unintentionally produced POPs. Unintentional POPs are substances which were not produced intentionally but form during the production of other chemicals. Examples for unintentionally produced POPs are dioxins or PCB. Among the POPs a group of substances which belong to hexachlorocyclohexanes (HCHs) are especially challenging to manage: alpha-HCH, beta-HCH, and Lindane (which is 99% gamma-HCH; Vijgen et al. 2019). Estimates of the amount of obsolete and waste alpha-, beta-, and gamma- HCHs are very high and exceed estimates of other obsolete pesticides (Vijgen et al. 2011). This is due to the fact that only one of the isomers (gamma-HCH) has insecticidal effects. During the production of Lindane, high amounts of other isomers formed during production. Uncontrolled disposal of these isomers caused serious environmental problems on former production sites and their surroundings; Fig. 3 shows a photograph of a disposal site of HCH-waste.

Stockholm Convention (2001), Fig. 3 Photograph of the landfill at Sabiñánigo, Spain, where large quantities of HCH waste from Lindane production were dumped in the past, resulting in serious environmental contamination of

the area around Sabiñánigo and the Gállego River. (Photograph taken by Malte Lessmann in 2015, used with permission)

As outlined in Article 8 of the Convention, new toxic and persistent chemicals which are transported over long distances can be added to the list of POPs. As the list of POPs can be enlarged, the Stockholm Convention has been described as dynamic (Kohler and Ashton 2011). At first scientists had raised the question whether the process of adding new chemicals was structured well enough to facilitate the addition of substances (e.g., Ballschmiter et al. 2002). However, since the adoption of the Stockholm Convention, the list of substances has been enlarged successfully. By 2017, 12 initial and 16 more recently added POPs were listed in the Annexes of the Convention. The current list of the Stockholm Convention POPs can be found on the website of the Convention (UNEP 2017b).

Impact of the Stockholm Convention

Recent evaluations of the Stockholm Convention conclude that the treaty is effective as a framework to regulate POPs on a global scale during their complete life cycle (UNEP 2017c, 2019). Monitoring data show that the regulations of the Stockholm Convention on POPs are successful, but the results differ for various POPs. For many of the initial POPs listed in 2001, reduced concentrations of POPs in the environment are reported. For more recently added POPs, environmental concentrations are slowly beginning to decline for some compounds, whereas for a few substances, the concentrations remain stable or increase (UNEP 2017c). For many of the initial POPs, the concentrations in human milk have also declined since the

Stockholm Convention entered into force, but for some of the persistent organic pollutants, concentrations in human milk are still too high (van den Berg et al. 2017). Unintentionally produced POPs and POPs waste will remain an ongoing challenge in the future (Liu et al. 2018). The open-ended listing of new persistent and toxic chemicals will require continued efforts to update national implementation plans and to start reducing the environmental concentrations of these substances.

The implementation of the Stockholm Convention is a stepwise process. It needs ongoing action and management in all signatory countries, as the management of POPs is a multi-sectoral problem involving different stakeholders. The Convention does not give different targets for developed and less developed countries. Specific circumstances in less developed countries need to be taken into account in scientific discussions by expert groups as well as during implementation in these countries (Wang and Sun 2016). Funding and technical as well as scientific assistance are required to implement the measures. Stockpiles in many countries have been addressed since the Convention came into force. Once POPs are released into soil and groundwater, removal or remediation costs increase substantially. Currently many contaminated sites remain, and legacies pose human health and environmental risks. Also they hamper the development of these locations (Bernhardt and Gysi 2016; Weber et al. 2008). The review process and assessment of new proposed candidate POPs require scientific review and information exchange. The conference has set up formal scientific bodies like the POPs Review Committee as well as more informal expert groups. Signing parties committed themselves to favor or conduct research as far as possible and to perform a monitoring of POPs concentrations. For some countries and regions, monitoring data are scarce. Also searching for alternative substances for POPs and gathering information on possible new candidate POPs require scientific exchange between parties. Therefore the Stockholm Convention can be seen as an international

agreement enhancing international scientific exchange (Magulova 2012).

Future Sustainable Chemicals Management

At the beginning of negotiations for the Stockholm Convention, there was a common understanding that global efforts were required to eliminate risks of persistent hazardous chemicals. Even though negotiations were difficult at times, there was a broad consensus that the treaty was a good basis for the implementation of improved chemicals management (Richter et al. 2001). Further challenges for the implementation of the Stockholm Convention include the assessment of industrial chemicals and the improvement of the implementation process. A large part of the signing countries has submitted national implementation plans; however data might be incomplete and still need to be updated for more recently added POPs. The existence of stockpiles and comparatively small progress with regard to the destruction of PCB indicates that ongoing efforts are required. This holds especially for industrial chemicals and more recently added POPs (UNEP 2017c, 2019).

The Stockholm Convention addresses chemicals and associated risks for stockpiles produced and released decennia ago. New initiatives of sustainable chemicals management aim at avoiding environmental risks, such as the ones related to the Stockholm Convention POPs, by suggesting a more sustainable approach to chemicals management. For chemicals and hazardous waste, the World Summit on Sustainable Development (WSSD) Johannesburg 2002 renewed the commitments made in Agenda 21. WSSD stated the following goal: “by 2020, that chemicals are used and produced in ways that lead to the minimization of significant adverse effects on human health and the environment” (Kath 2011). Direct progress regarding the actions mentioned in the Johannesburg plan of implementation could improve chemicals management, e.g., by strengthening synergies between Basel, Rotterdam, and Stockholm

Conventions, by promoting partnerships for effective and sustainable chemicals management, and by using national pollutant release and transfer registers for more transparency. Additionally, more progress could be achieved by uncoupling economic development and pollution or waste generation (Kath 2011). The expected growth of global population will require increasing food production in the future. This might lead to a growing demand for agrochemicals and/or an increasing demand for sustainable alternatives to chemicals. Alternatives currently discussed are integrated pest management, agroecological approaches, and biological crop protection.

Developing greener and more sustainable chemistry can help to tackle such challenges in the future (UNEP 2019). Some of the innovations and new inventions in chemistry in the past turned out to have negative effects on human health and the environment after more information became available. So, a combination of international treaties, science-based advanced assessment procedures for chemicals, and green chemistry innovations can provide tools to prevent hazardous chemicals reaching the market in the future.

Summary

The Stockholm Convention is a global agreement to reduce risks to human health as well as environmental risks caused by persistent organic pollutants. It was signed in 2001 and came into force in 2004. The Convention signatories need to restrict or eliminate the production and use of substances which are especially toxic and persistent. Also they need to reduce the releases of unintentionally produced POPs. The Convention also comprises provisions for environmentally sound management and the disposal of POPs waste. There are synergies with two other global treaties on chemicals management (the Basel Convention and the Rotterdam Convention). The list of substances is open-ended, new chemicals can be added. The implementation of the Convention shows positive effects for some substances. Continuing efforts are needed especially for

industrial chemicals and more recently added POPs.

Stockholm Convention on Persistent Organic Pollutants

► Stockholm Convention (2001)

Strategic Corporate Social Responsibility

Mark Anthony Camilleri ¹ and Benedict Sheehy²

¹Department of Corporate Communication, Faculty of Media and Knowledge Sciences, University of Malta, Msida, Malta

²Canberra Law School, University of Canberra, Canberra, Australia

Definition

Organizations engage in Strategic Corporate Social Responsibility (Strategic CSR) when they integrate responsible behaviors in their corporate practices (Camilleri, 2018; Porter & Kramer, 2011). Therefore, strategic CSR is often evidenced by the businesses' engagement with key stakeholders, including customers, employees, shareholders, regulatory authorities, and communities as their nonfinancial activities can have an effect on society and the natural environment (Camilleri, 2017a). The ultimate goal of strategic CSR is to create both economic and social value (Carroll & Shabana, 2010; Falck & Heblich, 2007).

Introduction

The businesses' CSR practices may result in a sustained competitive advantage if they are willing to forge strong relationships with their stakeholders (Camilleri, 2015a; Freeman & McVea, 2001). Therefore, businesses ought to communicate with employees, customers, suppliers, regulatory stakeholders, as well as with their

surrounding community (EU, 2016; Bhattacharya et al., 2009). Positive stakeholder relationships can lead to an improved organizational performance, in the long run (Camilleri, 2015a).

The most successful businesses are increasingly promoting the right conditions of employment for their employees, within their supply chains (Camilleri, 2017b). They are also instrumental in improving the lives of their suppliers (Camilleri, 2017c; Porter & Kramer, 2011). They do so as they would like to enhance the quality and attributes of their products or services, which are ultimately delivered to customers and consumers. Hence, their long-term investments on strategic CSR activities are likely to yield financial returns for them. At the same time, they will add value to society (McWilliams et al., 2006; Falck & Heblich, 2007). Therefore, the strategic CSR involves the promotion of socially and environmentally responsible practices they are re-aligned with the businesses' profit motives (Camilleri, 2017b, c).

Key Theoretical Underpinnings

The strategic CSR perspective resonates well with the agency theory. In the past, scholars argued that the companies' only responsibility was to maximize their owners' and shareholders' wealth (Levitt, 1958; Friedman, 1970). Hence, companies were often encouraged to undertake CSR strategies, which can bring value to their businesses and to disregard those activities which are fruitless. However, at times, the fulfillment of philanthropic responsibilities can also benefit the bottom line (Lantos, 2001).

Although, it could be difficult to quantify the returns of responsible behaviors, relevant research has shown that those companies that practiced social and environmental responsibility did well by doing good (Falck & Heblich, 2007; Porter & Kramer, 2011). Some of the contributions on this topic suggest that corporate philanthropy should be deeply rooted in the firms' competences and linked to their business

environment (Camilleri, 2015a, b; Porter & Kramer, 2002; Godfrey, 2005). Many authors often referred to the CSR's core domains (economic, legal, and ethical responsibilities) that were compatible and consistent with the relentless call for the business case of CSR (Camilleri, 2015b; Carroll & Shabana, 2010; Vogel, 2005).

Many commentators argued that the strategic CSR practices may result in a new wave of social benefits as well as gains for the businesses themselves (Fombrun et al., 2000; Porter & Kramer, 2011) rather than merely acting on well-intentioned impulses or by reacting to outside pressures (Van Marrewijk, 2003). Lozano (2015) indicated that the business case is the most important driver for CSR engagement. Thus, proper incentives may encourage managers "to do well by doing good" (Falck & Heblich, 2007). If it is a company's goal to survive and prosper, it can do nothing better than to take a long-term view and understand that if it treats society well, society will return the favor. Companies could direct their discretionary investments to areas (and cost centers) that are relevant to them (Gupta & Sharma, 2009). The reconciliation of shareholder and other stakeholders addresses the perpetual relationship between business and society, as companies are expected to balance the conflicting stakeholder interests for long-term sustainability (Orlitzky et al., 2011; Camilleri, 2017c; Camilleri, 2019).

Conclusion

Many companies are increasingly recognizing the business case for CSR as they allocate adequate and sufficient resources to financial and non-financial activities that will ultimately benefit their stakeholders. Their motivation behind their engagement in strategic CSR practices is to increase their profits and to create shareholder value. At the same time, they strengthen their competitive advantage through stakeholder management.

Description

Over the last 60 years, the relation between strategic management and corporate social responsibility has been evolving from opposition towards convergence. For decades, researchers representing the two fields have either expressed indifference toward the achievements of the other group or rejected them outright. While for strategic management scholars, CSR was little more than a luxury add-on that only most successful companies could afford (Freeman and McVea 2001), many business and society academics rejected any attempt to integrate the social and environmental dimensions of operational activities with core business strategy considering it simply unethical (Husted and Allen 2011). The two fields shifted towards convergence already in 1980s (Drucker 1984; Freeman 1984), but it was not until late 1990s (Lee 2008), when the link between strategic management and CSR began to be explored intensively and concepts around strategic CSR (see ► [“Strategic CSR”](#)) started to emerge, overcoming the traditional dichotomy between social and economic goals. The common denominator of these concepts is that they call for integration of CSR into core business strategy and development of business case for corporate social and environmental investment.

Strategic Management

The field of strategic management began to emerge in the 1960s. Strategic management is about the direction of organizations, in particularly business firms (Rumelt et al. 1994). It has traditionally focused on identifying the factors that affect firm performance (Hoskisson et al. 1999), more specifically the factors of success and failure among organizations (Guerras-Martín et al. 2014). Strategic management includes: the selection of goals; the choice of products and services to offer and the choice of firm’s competitive position in the product markets; the choice of the scope and diversity level; and the design of organizational structure, administrative systems, and policies that coordinate work (Rumelt et al. 1994).

Although definitions of the field vary to a large extent, there is an implicit consensus among scholars as to the meaning of strategic management. Based on the results of a lexicographic analysis of nearly 400 articles from the top management journals, Nag et al. (2007) identified six key elements that constitute the implicit consensual definition of strategic management: “The field of strategic management deals with (1) the major intended and emergent initiatives (2) taken by general managers on behalf of owners, (3) involving utilization of resources, (4) to enhance the performance (5) of firms (6) in their external environments” (p. 942). The first element refers to deliberate and planned initiatives (such as strategy development and implementation, acquisition, alliances, and diversification) as well as emergent activities of learning and innovation. The second definitional element explains, who are the key actors in strategy research. It concerns senior managers and governing bodies of companies, who operate as agents of the owners. The third element points to the internal and external resources that managers use in their strategic initiatives. The key objectives of strategic management including growth, advantage, dominance, returns, and performance are encompassed by the fourth element, while the focal unit of the analysis in the strategic management research is described by the fifth one. Strategy scholars focus

on the firm as a whole, be it single-business, multibusiness, multimarket, or multinational. Finally, the sixth element of the definition refers to the immediate environment of a firm (industry) as well as broader external contingency factors generating business threats and opportunities.

The field has attracted the interest of researchers representing different disciplines including economics, sociology, marketing, and management (Nag et al. 2007). Various theories and methodologies, addressing different research topics, have been developed to identify the factors driving success among firms (Guerras-Martín et al. 2014). The evolution of the field has been shaped by simultaneous movement of two pendulums (Guerras-Martín et al. 2014). First, inside-outside pendulum concerns the tensions between a firm's internal and external environment (Hoskisson et al. 1999). More specifically, while some strategic management scholars have focused on internal factors, such as strengths and weaknesses, that might explain firm's performance, others have tended to look at opportunities and threats in the external environment. Second, micro-macro pendulum refers to the tensions between two levels of analysis in the strategic management research, whether it is focused on identifying success factors at the firm (macro) level or on group/individual level (micro) (Guerras-Martín et al. 2014).

Corporate Social Responsibility

The early studies on CSR date back to the 1930s and the Harvard Law Review debate between Adolph A. Berle and Merrick Dodd on the subject of the proper purpose of the public corporation. On the one side stood Berle, who held the view that corporation exists to generate profit for its shareholders. On the other side, Dodd argued that corporation is as an economic institution that serves both society and shareholders (Stout 2002). Later, in the 1950s, the debate has spread to management studies (Crane et al. 2008).

At the core of CSR lay the issue of "social obligations and impacts of corporations in society" (Crane et al. 2008, p. 6). CSR is considered as

"a field of scholarship" (Crane et al. 2008, p. 6) without a paradigm that is still in the state of emergence (Lockett et al. 2006). Its definitions vary depending on the discipline. The literature concerning CSR is strongly siloed and encompasses various concepts, constructs, and theories that are at times in conflict with each other. While in economics researchers focus on CSR understood as a profit sacrificing activity (McWilliams and Siegel 2001), management scholars see it as a voluntary business strategy aimed at creation of shared value (Porter and Kramer 2011). In legal studies, some view CSR as the use of assets to benefit nonshareholder stakeholders (Sheehy and Feaver 2014), while others define it as "international private business self-regulation" focused on minimizing social harms of and contribution to social welfare by companies (Sheehy 2015). In political sciences, the understanding of CSR has been centered around corporate citizenship aimed at protecting citizens from government failures (Matten et al. 2003). Finally from institutional perspective, CSR is viewed as an organizational response to an institutional change embedded in growing social awareness and environmental limitations and supported by stakeholders pressure and regulation. Institutionalists define CSR as an emerging international business norm (Mühle 2011).

Opposition Between Strategic Management and CSR

Although origins of research on CSR in management studies date back to around the same time as beginnings of strategic management, the fields have been developing largely independently. On the one side of the argument, social and environmental issues were not completely ignored in the strategic management research, as they were taken into account as external factors influencing (mostly limiting) strategic options. However, strategic management scholars did not use the achievements of their business and society counterparts (Dąbrowski 2016). What is more, some strategists, particularly those with a strong economics orientation, considered CSR nothing but a

cost (Husted and Allen 2011) or an illustration of the **agency problem**, that is, managers misusing resources of the principals and acting in their own rather than shareholders' best interest (Friedman 1970). In this vein, from a strategic point of view, Karnani argues that whereas people acting as private citizens should do good, companies have only a responsibility to their shareholders to do well (Karnani 2011b), and adds that laws are much more effective than voluntary CSR at inducing firms to implement socially desirable behavior (Karnani 2011a).

On the other side of the argument, the classical understanding of CSR, constructed around notions such as voluntarism, social altruism, and profit sacrificing (Horrigan 2010, pp. 34–35), took a deontological approach. The view was that firms' obligations were ethical obligations to voluntarily engage in social activities. Within this altruistic approach (see ► **"Altruistic CSR"**), CSR is defined as "situations where the firm goes beyond compliance and engages in actions that appear to further some social good, beyond the interests of the firm and that which is required by law" (McWilliams et al. 2006). Firm motivation plays a crucial role in differentiating between strategic CSR, a type of CSR that is seen merely as a type of profit maximization strategy, and real, altruistic CSR that is motivated by ethical considerations. "If firm's motivation for social action is profit, then it is not social action but simply good business" (Husted and Allen 2011, p. 37).

Towards Convergence

The fields began to draw closer in the 1980s, and although some scholars continue to take adversarial positions between them, to a large degree significant advances have come from this trend. Some authors argue that in the increasingly complex and turbulent business environment, companies' ability to grow and to improve continuously is also a function of its social competencies, ethical responsibility, and environmental contributions (Hardjono and Marrewijk 2001). Creation of shareholder value alone is slowly giving way to a broader, more holistic view of organization and

its performance (Beltratti 2005). The paradigm of shareholder wealth maximization, however, is not only not supported by strategic rationales but has also proved to be detrimental to the shareholders themselves (Stout 2012). As a result, strategic management scholars started to recognize corporate social responsibility as an important factor contributing to corporate long-term success.

The link between strategic management and CSR began to gain attention in academic community in the 1980s. One of the first strategy scholars, who pointed at the complementary relationship between the fields, was Drucker (1984). Drucker argued that CSR was compatible with profitability and that social responsibilities could be converted into business opportunities. "The proper 'social responsibility' of business is to tame the dragon, that is to turn a social problem into economic opportunity and economic benefit, into productive capacity, into human competence, into well-paid jobs, and into wealth" (Drucker 1984, p. 62). This strategic approach to CSR has been developed in later years by Porter and Kramer (2002, 2006, 2011). In a series of articles for the Harvard Business Review giving birth to the concept of creating shared value (CSV), authors argued that in a world of open, knowledge-based competition social and business goals form a symbiotic relation (see ► **"Porter and Kramer's (2006) 'Shared Value'"**).

What is more, since the 1980s there has been a growing number of business and society scholars (Freeman 1984; Hart 1995; Husted and Allen 2011; Visser 2012) who call for integration of CSR into core business strategy. They argue that the anticapitalistic image of CSR has led to its marginalization in the eyes of many managers and scholars. They note that traditional CSR (despite its noble intentions) has become "a confusing cliché which cheats consumers and society at large" (Ahen and Zettinig 2015, p. 95). Porter and Kramer (2006) claim it is cosmetic, "overly narrow, passive and a disguise for causing harm" (Ahen and Zettinig 2015, p. 95), primarily motivated by possible reputation gains. This problem resulted in corporate social responsibility being perceived "as an 'add-on' luxury that can be only afforded by the most successful businesses,

or as a damage limitation insurance, rather than as a core element of the business strategy” (Freeman and McVea 2001, p. 7). Thus, as Ahen and Zettinig (2015) argue, the existence of genuine CSR without being embedded in strategy has been challenged.

CSR initiatives have evolved from philanthropy to strategies that integrate social and environmental issues into firms’ core business operation through innovation (Gugler and Shi 2009). Strategic CSR does not aim at removing the firm from the economic landscape, but at aligning business goals with those of the society for co-created and shared value (Ahen and Zettinig 2015). Linking social and environmental activities with long-term strategic goals offers prospects of greater credibility and value added, since a company can impact its stakeholders in more meaningful ways by tapping its unique capabilities and tailoring to the local context (Jamali 2007).

Business Case for CSR

The strategic shift in CSR research has spurred search for **business case for CSR**. “A ‘business case’ is ‘a pitch for investment in a project or initiative that promises to yield a suitably significant return to justify the expenditure’” (Carroll and Shaban 2010, p. 92). In regard to CSR, business case refers to the potential positive impact of corporate social performance (CSP) on corporate financial performance (CFP) (Carroll and Shaban 2010). The literature provides various rationales for how CSR improves organization’s bottom line (detailed discussion on CSR-related sources of competitive advantage can be found in entry ► “Strategic CSR”). These include differentiation (Cruz et al. 2015), human resources advantages (lower labor costs and higher productivity) (McWilliams and Siegel 2011), support from external stakeholders (i.e., government, local communities, suppliers, advocacy groups, investors) (Fombrun et al. 2000), avoiding regulation costs (Mullerat 2010), and innovativeness (Porter and Kramer 2011).

Conceptual research on the strategic implications of CSR has been accompanied by empirical

studies seeking evidence for the existence of CSR business case. These studies have focused mostly on the empirical research linking CSR and financial performance (CFP) (Carroll and Shaban 2010). Despite the enormous academic effort to investigate the relationship between these two dimensions of corporate performance, the studies still provide inconclusive results (Lu et al. 2014). On the one hand, Orlitzky et al. (2003) summarize this relationship using meta-analysis of 52 studies while adjusting for sampling and measurement errors. The results show that, across the existing studies, CSR is positively related to financial performance. However, available studies do not provide clear results concerning the direction of the causation between CSR and financial performance. In other words, it is unclear whether companies “are doing well by doing good” or “are doing good, because they’re doing well” and have sufficient resources to invest in CSR. Similarly, the results of the meta-analysis conducted by Margolis and Walsh (2003) and Margolis et al. (2009) indicate that the overall weight of the studies shows a positive but weak correlation between CSR and financial performance. On the other hand, in another meta-analysis, Wang et al. (2015) estimated that the overall effect size of the CSR–CFP relationship is positive and significant. It is, however, stronger for firms in developed economies than for firms from the emerging ones. What is more the authors show that subsequent financial performance is associated with prior social responsibility, while the reverse direction is not supported. These results support the “doing good by doing well” hypotheses.

Reasons for the mixed results include inconsistency in defining and measuring CSR and firm performance, inconsistency in samples, imprecision and inconsistency in research design, omitted variable problems, a lack of necessary analyses of causality and/or endogeneity, a lack of methodological rigor, and a lack of theory (Margolis and Walsh 2003; McWilliams et al. 2006). Firm performance is influenced by many variables simultaneously, what makes it difficult to isolate just the CSR impact (Husted and Allen 2007). Orlitzky et al. (2011) conclude that empirical evidence regarding the potential strategic benefits of CSR

should be interpreted with caution for two reasons: (1) inconsistencies between CSR ratings used as a measure of corporate social performance and actual outcomes that result in loss of stakeholder trust towards companies' social and environmental efforts; and (2). low paradigmatic consensus in CSR research.

Despite the lack of clear, quantitative evidence for the positive influence of corporate social and environmental investment on organizational performance, there is strong consensus in the literature that nonmarket issues can have a substantial impact on company's competitiveness. However, the relationship between CSR and strategic management goals is not automatic or, in other words, not every CSR investment translates into business success. A business case for CSR has to be created proactively through intelligent design of voluntary activity that contribute to the solution of societal or environmental problems and, in the same time, have positive measurable business effect (Michelon et al. 2013). Most of the companies have potential for one or several business cases for CSR. This potential is often not recognized because of distorted accounting and management information systems and other organizational rigidities.

Some argue that the positive effect of CSR initiatives on financial performance strengthens, when a company pursues CSR initiatives that are linked to preferences of its most salient stakeholders and allocates resources to these initiatives in a strategic way (Michelon et al. 2013). Husted and Allen (2007) contend that payoffs of engaging in CSR are contingent upon the fitness of social activities with certain firm characteristics. CSR activities designed in such a way help firms develop intangible, valuable, and difficult to imitate assets, which can be a source of competitive advantage.

Summary

In the 1980s, the indifference and opposition between strategic management and CSR scholars started to shift towards mutual understanding and cooperation. While the former recognized CSR as

a source of competitive advantage and long-term value driver, the latter acknowledged that CSR programs without strategic focus have little potential to generate virtual social change. The trend towards convergence between the two fields has opened up new avenue for research exploring the link between CSR and organizational performance. The inconsistent results of these studies show that not all social and environmental activities translate into enhanced corporate financial performance, suggesting need for further inquiry into effective integration of CSR with core business strategy.

Strategy in a Circular Economy: Discussion of Opportunities and Limitations

Helen Kopnina and Alistair Bowden
Northumbria University, Newcastle upon Tyne, UK

Synonyms

[Business model perspective](#); [Closed-loop production](#); [Cradle to Cradle](#); [Product-to-service shift](#)

Definition

A closed-loop production, also called Cradle to Cradle or “circular economy,” offers to fundamentally rebuild the current take-make-waste system of production (McDonough and Braungart 2010).

The aim of the circular economy is twofold: on the demand side, to eliminate the need for new resources, and on the supply side, to achieve a product-to-service shift through rental and repair rather than ownership. Therefore, business model innovation of inputs, processes, and relationships with end-users is necessary at an organizational level (Bocken et al. 2014, 2016; Kindström 2010). A business model perspective on organizational strategy is particularly relevant to the circular economy as it focuses on both a strategic and operational level, including designs, products, processes, values, and wastes as key concepts that might normally be ignored by more corporate strategic management (Bocken et al. 2014). There are at least two critical differences in implementing business model innovation in a circular economy. First is the essential importance of initial design that enables a circular flow (Centobelli et al. 2020; Urbinati et al. 2017). Second is the joined-up and inter-dependent nature of supply chains and value networks (Lieder and Rashid 2016), which requires more intense consideration of more diverse, and perhaps initially unwilling, stakeholders, including shareholders, employees, clients, suppliers, society, environment, and government (Geissdoerfer et al. 2018a).

Introduction: Key Concepts and Debates

This Encyclopedia entry discusses the opportunities and limitations of the so-called circular or closed-loop production systems in business.

Sustainability experts within corporate contexts increasingly recognize that environmental problems, from climate change to biodiversity loss and pollution, are caused by social and economic factors, such as an increase in population, production, and consumption (O'Sullivan 2020). A closed-loop production, also called Cradle to Cradle (C2C), or "circular economy" offers to fundamentally rebuild the current take-make-waste system of production (McDonough and Braungart 2010). Reusing materials and increasing the durability of products already in use promise to counter the throw-away culture of planned or built-in obsolescence (Bulow 1986).

Ideally, a circular system aims not just to increase the level of material and energy recovery but to eliminate the continuous need for new and often scarce resources (De Man and Friege 2016; Kopnina 2021). This aim is facilitated by the calls to accelerate the "product-to-service shift" (PSS) or dematerialization of product use through rental and repair rather than ownership, which requires the re-organization of business through the transition from selling to leasing or pay-per-use schemes (Savini 2021; Stevens et al. 2021). In some conceptions, a circular economy can be seen to criticize the folly of using up our non-renewable resources ("capital" in economist terms), like the "small is beautiful" critique of mass production (Schumacher 1973). Notably, as will be discussed in more detail below, the circular economy is associated with growth, or "large is beautiful."

C2C, which may be said to be one of the "inspirations or design principles underlying circular economy," identifies three key principles of alternative production systems: (a) waste equals food, (b) use current solar income, and (c) celebrate diversity. *The waste equals food principle* emphasizes that unproductive waste should be eliminated. A fruit tree's "waste" provides nutrients for other species or soil when decomposed. *The use of renewables principle* supports the sun and wind energy, which, aside from installation, storage, transmission, and maintenance, are immaterial and relatively infinite. *Celebrate diversity* refers to natural systems that support complex biodiverse communities, or ecosystems, where each member has developed a unique response to its surroundings that works in concert with other organisms. Considering the discussion of limitations of the circular economy, it is worth noting that in the definition of the Convention on Biological Diversity, "Biological diversity" means the variability among living organisms from all sources, including terrestrial, marine, and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species, and of ecosystems (CBD 2023).

C2C products take nature's diversity as a prototype for tailoring designs to maximize their

positive effects and enhance the local landscape (McDonough and Braungart 2010). Biomimicry designs, for example, imitate the complexity of natural forms, as well as their function and reciprocity with other natural elements (Stevens et al. 2021). These principles are translated into the C2C certification, which awards products an achievement distinction in the categories of Material Health, Material Reutilization, Renewable Energy, Water Stewardship, and Social Fairness. The products could achieve a Basic, Bronze, Silver, Gold, or Platinum level, with the lowest achievement level representing the product's overall mark (Cradle to Cradle Certified 2020). Various companies have developed metrics used to define a material based on its properties such as recyclability, scarcity, and toxicity (e.g., <https://www.metabolic.nl/news/the-seven-pillars-of-the-circular-economy/>).

Circular economy evaluations using the 10-R scale and C2C accreditation are aimed to evaluate the inputs of production (raw materials, energy, etc.) associated with all the production outputs, use, and disposal (Kirchherr 2022; Ünal and Shao 2019). The 10-R scale starts with the R of Refuse, which implies avoidance of production and consumption in the first place, and is followed by the Rs of Rethink, Reduce, Reuse, Repair, Refurbish, Remanufacture, Repurpose, Recycle, and Recover (Potting et al. 2017).

However, as good as they sound, circular frameworks can be subverted into the business-as-usual growth economy model. The popularity of the idea that recycling and eco-efficiency and, even more so, infinite reuse of products can serve as a “new engine of growth” can be explained by the fact that much of circular economy terminology if not practiced was jumpstarted by the reports of the Ellen MacArthur Foundation. The circular economy continues to be significantly intertwined not necessarily with career academics but with practising academics receiving at least some funding from corporate partners, or “pracademics” and practitioners (Kirchherr 2022). It was noted that the circular economy's success in business and policy circles rests upon the promise that circularity is central to sustainable development promising to marry a growth

economy (and corporate profit) with sustainability (Kirchherr 2022). As the section below explains, this can be problematic.

The Challenges of Greenwashing

Precisely because the circular economy promises to support growth and supporting corporate optimism, it also opens the door for greenwashing (Kirchherr 2022; Kopnina and Benkert 2022). McDonough and Braungart's book, *The Upcycle* (2013) illustrates this optimism by suggesting that the production of the “right” products can add value and have a net positive effect on ecosystems. However, using the CBD's definition of biodiversity, it is unclear as to how any human designs, used for utilitarian purposes, can contribute to the functioning of ecosystems, considering that these ecosystems far predate human industry. There is an ethical and pragmatic difference between socio-economic and cultural changes due to biodiversity loss and extinction that terminates not just millions of lives of individuals within the species, but entire species (Kopnina et al. 2018). Thus, the discussion of upcycling and net positive effects may be part of nothing more than marketing, carrying the danger of complacency of both companies and consumers to the easy promises of cleaner production.

A social anthropologist specializing in cultural and social barriers to sustainable/green behavior, Cindy Isenhour (2010) notes that individual consumers might be either uninformed or unmotivated, or tricked by the supposedly “green” marketing that stimulates the consumption of new products, causing a rebound effect. Also, consumer responsibility rhetoric can be seen as a strategy of corporate and political leaders to “defend their ability to resist the regulation of resource-intensive, polluting or socially damaging products” (Isenhour 2010, p. 456). A distinction between ideal, realistic, and subverted circular practice is helpful (Kirchherr et al. 2017).

The companies that get certified as Cradle to Cradle (C2C) (<https://www.c2ccertified.org/get-certified/product-certification>) or placed on the

list of “good practice” of the MacArthur Foundation (https://ellenmacarthurfoundation.org/case_studies) often still focus on merely minimizing damage, not radically eliminating it. The “best case practices” by the Ellen Macarthur Foundation include Coca-Cola and other corporations, which stimulate downcycling, rather than infinite reuse (Kirchherr 2022; Kopnina 2021).

While the first R of circular economy is *Refuse*, the use of virgin or downcycled materials and not fully reused existing ones is common with manufacturers that improve their production only marginally, without the needed overhaul of the *entire* supply chain as mode of operation. Also, sustainability specialists have identified opportunities for the so-called “post-growth” circularity that reaches beyond growth fetishism, emphasizing the downscaling of the economy to make it consistent with biophysical boundaries via the application of the R principles (Bauwens 2021; Kirchherr 2022). Another concern is dubbed the “circular economy rebound,” meaning that expected savings from the circular economy may be invested unsustainably, thus offsetting any sustainability benefits previously accrued (Kirchherr 2022; Zink and Geyer 2017).

As argued by critical assessors, in the circular economy, it is thus crucial to make a distinction between ideals and practice but also underline the limitations of the very concept of circularity (Bauwens 2021; Carus and Dammer 2018; de Man and Friege 2016; Holmes et al. 2021; Johansson and Henriksson 2020; Kirchherr 2022; Kopnina 2021; Kopnina and Padfield 2021), distinguishing between biological/organic cycle products. de Man and Friege (2016) note that waste is rarely “food” as any consumed food literally changes into toilet waste, which is not the same in nutritional value as injected components. Also, both the method of food production and the type of food produced, e.g., the climate-related differences in the locally grown laboratory meat versus soya-based meat substitutes, need to be considered, if the “waste is food” principle is to be followed (Kopnina et al. 2023). Within the technological cycle, where products can be evaluated by the 10-R strategy, different

considerations will apply (such as durability and potential for infinite reuse of materials).

There is also a question of whether a circular economy is competitive with a post-growth or degrowth strategy that some of the more forward-looking sustainability specialists bring into doubt (Bauwens 2021; Hofmann 2022). As Bauwens (2021, p. 219) states:

While the circular economy is a popular topic on many countries’ political agendas, an expanding body of empirical evidence shows that, thus far, increases in the global gross domestic product (GDP) have been tightly coupled with an increase in the size of the material footprint and associated ecological impacts of the economy (Hickel and Kallis, 2019). Global absolute decoupling of GDP growth and resource consumption (i.e., a decline in the global material footprint in absolute terms while the global GDP continues to increase), a necessary condition for green growth, is still far from a reality.

Yet, while it still has a long way to go in practice, a circular economy can be potentially transformative.

Strategic Ways Forward

Kirchherr (2022) reflects that some post-growth or degrowth discourses, in combination or independent of circular economy thinking or not, may be unrealistic and undesirable as they would hamper the development of alternative economies (that ironically need to grow to replace linear or unsustainable ones). Kirchherr (2022) states that while calls for the economy to be “small-scale and localized to primarily serve local communities’ needs” may sound romantic and desirable, harking back to the “small is beautiful” ideals (Schumacher 1973), “this may equate with a detour to the Middle Ages.” This point of critique might be especially relevant as a few billion consumers have been born since Schumacher’s famous volume has first been published. Kirchherr offers both caution and hope as far as the strategy of circular development is concerned:

Once rapid growth of circular businesses has occurred, with these companies driving linear players out of the market, the economy may be, measured in GDP, smaller than its linear

predecessor, if dominant products are ultra-durable and/or more resource efficient. This economy may also be larger, though. After all, consumers tend to re-invest savings induced by CE (think of savings occurring because of an ultra-durable smartphone that suddenly lasts 10 years). . . . However, it is conceivable that these savings are re-invested sustainably (think of a weekend get-away at an eco-farm close-by), setting off a perpetuum mobile towards sustainability. We just do not know. (Kirchherr 2022)

Good examples of what type of products can be seen as worth re-invested savings can be found in pre-industrial production systems, for example in vegan diets, or clay containers that used to be used for transportation and storage.

Strategic Action at Multiple Levels

Unlike traditional, market-based strategy which is focused on discrete organizations in a competitive environment, strategy in a circular economy is inter-organizational and multi-level: individuals, small- and medium-sized enterprises, multinational enterprises, industry representative bodies, local government, charities and nongovernmental organizations, and nations and supranational organizations all have roles to play in enabling circularity (de Jesus and Mendonça 2018; Geissdoerfer et al. 2020; Ghisellini et al. 2016; Kalmykova et al. 2018; Lieder and Rashid 2016). The following summary will focus on the three levels that have attracted particular attention in the circular economy literature so far: national and supranational policies, circular business models, and intrafirm dynamic capabilities.

At the highest level, much has been written about the contrasting approaches being taken toward the circular economy in China and Europe (Ghisellini et al. 2016; McDowall et al. 2017). China's rapid growth from the 1970s onwards had been built on intense industrialization and urbanization, heavy exploitation of natural resources, production processes with weak environmental oversight, and utilizing inefficient methods, leading ultimately to environmental damage, social problems, and a slowing economy (Su et al. 2013). Building on several preceding

initiatives, the Circular Economy Law Promotion that came into force in 2009 produced a comprehensive national approach and mandated action at all levels of government and industry across China (Mathews and Tan 2011; McDowall et al. 2017). This is perhaps the most obvious example in a circular economy context of a traditional top-down, deliberate strategy. However, in common with the mainstream academic strategy literature (e.g., Friesl et al. 2021; Hrebiniak 2013; Weiser et al. 2020), the Circular Economy Law Promotion has faced barriers to implementation and enforcement at local levels (Ranta et al. 2018). There were policies on resource recycling and reuse, cleaner production, pollution, and waste but perhaps most significantly on place-based planning interventions (McDowall et al. 2017; Zhu et al. 2019). Eco-industrial parks, supported by various national government departments and regional and municipality authorities, are a particularly powerful method in China's top-down approach, incentivizing firms to co-locate in planned zones and to innovate their processes to reuse waste resources and use energy efficiently (Homrich et al. 2018; Mathews and Tan 2011; McDowall et al. 2017).

Europe has taken a different approach from China. It is more focused, in that it concentrates more on minimizing virgin natural resource exploitation and waste minimization while also supporting sustainable economic growth (Domenech and Bahn-Walkowiak 2019; Ghisellini et al. 2016). It is more bottom-up, in that it uses policy, regulation, and finance as incentives to nudge organizations toward 10-R activities (and disincentivize linear cradle-to-cradle activities) but has not utilized planning tools to manipulate spatial re-arrangements in supply chains (McDowall et al. 2017). In addition, while China has concentrated on supply issues, European countries are far more focused on changing consumers into users (Lazarevic and Valve 2017). Therefore, while the European Commission (2015) has developed a high-level policy in this area – *Closing the Loop: An EU Action Plan for the Circular Economy* – this is more catalytic than a deliberate plan. Therefore, most of the European literature on strategy in the

circular economy is focused on lower levels of analysis.

A thorough definition is given by Bocken et al. (2014, p. 43): “Business models are concerned with how the firm defines its competitive strategy through the design of the product or service it offers to its market, how it charges for it, what it costs to produce, how it differentiates itself from other firms by the value proposition, and how the firm integrates its own value chain with those of other firm’s in a value network.” Therefore, a business model perspective on organizational strategy is particularly relevant to the circular economy as it focuses on both a strategic and operational level, including design, products, processes, and value (and waste) as key concepts that might normally be ignored by more corporate strategic management. Some archetypes of circular business models emphasize the way that value is added (and waste avoided) as a basis for competitive and collaborative advantage: closing (recycling), extending (prolonging usability through repair and reuse), intensifying (gaining more use in a shorter period), narrowing (using fewer resources by being more efficient), and dematerializing (product substitution by service and software solutions) (Bocken et al. 2016; Geissdoerfer et al. 2018a).

Other typologies emphasize different relationships: different ownership, manufacturing and maintenance relationships, location of operations, customer use (single sequential, parallel), and payment models (Tukker 2015). Still, others emphasize the technological, social, and organizational dimensions of circular business models (Bocken et al. 2014). But as with most strategies, it is not the vision that is the tricky bit, it is the implementation (e.g., Friesl et al. 2021; Hrebiniak 2013; Weiser et al. 2020). Therefore, the literature on circular business model innovation is particularly important to a successful transition to a circular economy. Geissdoerfer et al. (2018b) propose four types: start-up (new business model for a new business), business model transformation (change the existing business model), business model diversification (add a new business model(s) to an existing one), and business model acquisition (purchase another business with a

desired business model). Apart from the “born circular” start-up, the other three business model innovation types involve strategy implementation, change management, and integration of new business units, on which there is well-established literature.

There are at least two critical differences in implementing business model innovation in a circular economy. First is the essential importance of initial design that enables a circular flow, characterized as four designs for X practices: a design for recycling (DfR), design for remanufacturing and reuse (DfR), design for disassembly (DfD), and design for environment (DfE) (Centobelli et al. 2020; Urbinati et al. 2017). Second is the joined-up and inter-dependent nature of supply chains and value networks (Lieder and Rashid 2016), which requires more intense consideration of more diverse, and perhaps initially unwilling, stakeholders, including shareholders, employees, clients, suppliers, society, environment, and government (Geissdoerfer et al. 2018a). This places special emphasis on multinational enterprises that have powerful positions in long and complex global supply chains, exemplars being members of the Ellen MacArthur CE100 Network (Urbinati et al. 2017), to act as catalysts to circular supplies globally.

At the lowest level of analysis, the emphasis has been on capabilities and, more specifically, on dynamic capabilities. A number of highly cited articles highlight that organizational capabilities are significant (e.g., Bocken et al. 2014; Boons and Lüdeke-Freund 2013). However, few studies have attempted to peer inside this black box to analyze these important capabilities in any detail. The work by Sehnem et al. (2022) is an example of a study that highlights some of the important capabilities that are required, particularly dynamic, relational, absorptive, and (eco)innovation and business model innovation capabilities. Linking back to the previous point that implementing strategy generally and carrying out circular business model innovation specifically are more problematic than formulating a new strategy, several papers have focused on the significance of dynamic capabilities: sensing, seizing, and reconfiguring (e.g., Marrucci et al. 2022).

Khan et al. (2020) list a series of activities linked to each: sensing involves activities such as identification of customer needs, tracking new market trends, and analyzing competitors' actions; seizing involves strategy formulation, finding strategic partners, planning investments, and planning requisite HR, among other activities; while reconfiguring involves activities like mergers and acquisitions, organization redesign, and acquiring plant and know-how. Inigo et al. (2017) also argue that dynamic capabilities can be split into those which encourage evolutionary or radical business model innovation. Using the sensing dynamic capability to illustrate their point, evolutionary activity might include holding stakeholder dialogs, anticipating and responding to regulations, and creating sustainability-related associations, whereas more radical activities emphasize focusing attention on critical and disruptive stakeholders and technologies. Finally, Wade et al. (2022) highlight that the activities constituting dynamic capabilities may develop through time. Using the reconfiguring dynamic capability as an example, early on prototype products may be released and new business models may be developed, followed by business model execution, then changing external industry expectations, and finally business model evolution and building credibility.

Summary

A circular economy is a simple, yet bold idea. It aims to minimize – better still, eradicate – the need for new natural resources, by shifting from an exploitative, take-make-waste production system to a closed-loop, cradle-to-cradle industrial ecosystem. This is in part achieved through the design of modular, decomposable products, which use less resources and are more durable and, at the end of their extended use, can be broken up into parts which can themselves be re-utilized. But this technological innovation also needs to go hand in hand with social innovation, involving a product to service shift away from ownership, toward rental and repair. All of this can be summarized

by the 10-R activities that individuals and organizations, at many levels and in many places, need to engage in to enable a successful circular economy to emerge: Refuse, Rethink, Reduce, Reuse, Repair, Refurbish, Remanufacture, Repurpose, Recycle, and Recover.

Ideally, a circular economy approach places overcoming environmental problems, such as climate change, biodiversity loss, and pollution, centrally in economic planning and organizational strategy. This involves diverse stakeholders who must act coherently at multiple levels. From a more top-down perspective, supranational, national, regional, and local governments must provide a context in which a circular economy can emerge, through legal frameworks, regulation, planning, incentives, and education. In contrast from a more bottom-up, organic perspective, organizations need to develop the capabilities and circular business models and more importantly the dynamic capabilities to constantly adapt through business model innovation, which can underpin the 10-R activities across complex global supply chains and among rapidly developing societies.

Synonyms

Rigorous sustainability

Definition/Description

The concept of sustainability includes a spectrum of perspectives ranging from a technocentric “very weak sustainability” position through to an ecocentric “very strong sustainability” one (Gibbs et al. 1998). Nowadays, it has been emphasized qualitative side of growth and strong sustainability (rigorous sustainability) position gearing to the green economy and environmental protection (Davies 2013). Environmental protection is seen to be crucial because certain natural

resources, e.g., “critical natural capital,” are irreversible (Neumayer 2003; Turner 1993), provide some functions, and are not substitutable by produced capital (Balaceanu and Apostol 2014; Klarin 2018). Their loss reflects on all other forms of capital (Neumayer 2003; Turner 1993). Critical natural capital is stressed by defining sustainability as leaving a stock of natural capital for the future generations as big as enjoyed by the current generation (Cabeza Gutiérrez 1996).

Strong sustainability position has various variants such as “environmental” and “ecological sustainability” (Pezzey and Toman 2005; Turner 1993). Environmental sustainability is focused on maintaining the factors and practices that contribute to the quality of environment (BusinessDictionary 2018a) which is necessary for conducting the economic activities and quality of life of people on a long-term basis (Elkington 1994). Ecological sustainability is focused on protection and restoration of the integrity of the Earth’s ecological systems (Bosselmann 2017) for maintaining their essential functions and processes and retaining their biodiversity in full measure over the long term (BusinessDictionary 2018b). “Very strong sustainability” position again stresses steady-state economic system based on thermodynamic limits and constraints and minimization of matter and energy throughput (Davies 2013; Turner 1993).

Introduction

An outline of a strong sustainability position is presented by Daly (1990). According to him, next principles are essential for sustainable development:

- The human scale should be limited to the level which, if not optimal, is at least within carrying capacity and therefore sustainable.
- Technological progress for sustainable development should be efficiency increasing rather than throughput increasing.
- Renewable resources should be exploited on a sustained-yield basis.

- Nonrenewable resources should be exploited at a rate equal to the creation of renewable substitutes.

From this perspective flow different variants of the precautionary principle (Howarth 1997) which constrain resource degradation or depletion.

The need to develop sustainability indicators is central when assessing whether an economy is sustainable or not. Within the field of economics, this search for an operational definition of sustainable development has led, among many other contributions, to the concepts of weak and strong sustainability (Cabeza Gutés 1996). The basic difference between a weak and strong sustainability position is the ability to exchange between different types of capital, which creates a source base for the satisfaction of human needs and desires. Total capital is considered to be aggregated and an umbrella association of components of natural, economic, and social capital (Hediger 2000).

Weak sustainability implies a constant amount of total capital assets (resources) over the time, while natural and produced (manmade, manufactured) capital are interchangeable (Solow 1986, 1993). According to Hediger (2000) natural capital is defined as the base of the natural resources in a specific geographic area. It consists of the capital of the ecosystem or environmental capital, which includes the stock of renewable resources (currently used and also unused in economic processes), partially cultivated and natural soil, as well as the environmental factors that

are necessary for the functioning of ecosystems. It determines the overall quality of the environment in the area and stocks of nonrenewable resources (Hediger 2000).

Strong sustainability (rigorous sustainability) position regards natural capital as providing some functions that are not substitutable by produced capital (Balaceanu and Apostol 2014; Klarin 2018; Turner 2000). These functions, labeled “critical natural capital,” are stressed by defining sustainability as leaving the future generations a stock of natural capital not smaller than the one enjoyed by the present generation (Neumayer 2003; Turner 1993). The weak and strong concepts outlined above can be considered to represent two opposing ends of sustainability. This entry focuses on the second of these views (Table 1).

Key Issues

Strong sustainability position stresses sustainability in terms of nondecreasing natural capital. Irreversible losses of environmental assets should be avoided because some elements of the natural capital stock are not substitutable by produced capital (Balaceanu and Apostol 2014; Klarin 2018; Turner 2000). For example, biogeochemical cycles cannot be replaced, and they are essential for human life (Turner 2000). Those ecological assets which are essential are called “critical natural capital” (Neumayer 2003; Turner 1993). Other multifunctional ecological assets, such as landscape, space, and relative peace and

Strong Sustainability, Table 1 Features of strong and very strong sustainability position (Davies 2013; Gibbs et al. 1998; Howarth 1997; Neumayer 2003; Turner 1993, 2000)

Perspectives	Biocentric	Ecocentric
Sustainability labels	Strong System as one element, changes as a whole	Very strong (deep ecology) A “cultural” change; external as well as internal elements of system altered
Green labels	Resource preservationist position	Extreme preservationist position
Ethics	Extension of ethical reasoning; collective interests take over individual interests	Acceptance of bioethics Intrinsic value in nature (i.e., valuable in its own right)
Type of economy	Deep green economy; no economic and population growth	Very deep green economy; heavily regulated to minimize “resource-take”

quiet, are not essential for human survival, but they are considered important for human well-being (Turner 2000). Advocates of strong sustainability position see that ecosystem functions and services mentioned above cannot be adequately valued economically. They also argue that a “system” is to be thought as one element, which changes as a whole (Davies 2013). Strong sustainability position represents preservationist position (Davies 2013) and recommends the avoidance of those options which may generate the worst outcomes and encompasses the precautionary principle (Turner 2000). Conservation of natural capital and the application of the safe-minimum standard are therefore important components of a strong sustainability strategy. The safe-minimum standard for biological diversity illustrates the practical steps that could be taken to increase the likelihood that the economy is sustainable (Bishop 1993). Extinction threatens sustainability because it may affect the stability of economically important ecosystems and it may entail losses of plants, animals, and microorganisms that would otherwise have become important resources in the future (Turner 2000). The practical, scientifically valid, and ethical goal of business is to systematically and proactively maintain “the possibility that human and other life will flourish on the earth forever” (Ehrenfeld 2000, p. 36). Strong sustainability demands an understanding of the “macro-economy as a sub-system of the finite ecosystem” (Neumayer 2013, p. 28) based on natural science. “Strongly sustainable” business should be shaped by the systems thinking natural, social, economic, and psychological scientific knowledge. It should proactively create conditions that together resolve the underlying causes of the “global problématique” (Özbekhan 1970).

The strong sustainability rule requires that at least critical natural capital must be protected as an important part of the capital bequest (Daly 1995). Providing future generations with a set of life opportunities that is undiminished relative to the present may be construed as an ethical duty that is grounded on a contractarian view of distributive justice (Howarth 1997). Collective interests take over individual interests (Davies 2013). According to Turner (2000), strong sustainability

position recognizes constraints on substitution processes and incorporates ethical concerns such as intergenerational equity as a moral duty. Strong sustainability is thus a normative and ethical concept rather than an analytical and operational one (Dietz and Neumayer 2007). According to Ayres et al. (2001), it rejects the optimism based on a continuous growth, the prices market dynamics, and the environment’s adaptable character. It emphasizes the idea that sustainability is the equivalent of the ability of providing to the following generations the same level of non-renewable resources and/or quality of environment than enjoyed by the present generation (cf. Cabeza Gutes 1996). What concerns the growth, the strong sustainability, is focused on aspects that are related to quality of life (Daly 1990; Ayres et al. 1998). Thus no economic and population growth is allowed (Davies 2013). Those who believe in the non-substitutability of natural capital support strong sustainability.

Strong sustainability position has various variants such as “environmental sustainability” and “ecological sustainability” (Pezzey and Toman 2005; Turner 1993). Morelli (2011) has discussed the concept “sustainability” related to the concept “environmental sustainability” in his article *“Environmental Sustainability: A Definition for Environmental Professionals* particularly regarding the importance of valuing ecological services and recognizing people’s interconnectedness. Taking into account the ideas presented by *Our Common Future* (WCED 1987), he has defined the concept “environmental sustainability”:

As meeting the resource and services needs of current and future generations without compromising the health of the ecosystems that provide them, ...and more specifically, as a condition of balance, resilience, and interconnectedness that allows human society to satisfy its needs while neither exceeding the capacity of its supporting ecosystems to continue to regenerate the services necessary to meet those needs nor by our actions diminishing biological diversity. (Morelli 2011, p. 6)

From the economic point of view, environmental sustainability is focused on maintaining the factors and practices that contribute to the quality of environment (BusinessDictionary 2018a) which is necessary for conducting

the economic activities and quality of life of people on a long-term basis (Elkington 1994). “Environmental” economics has considered as opposed to “ecological” economics (Pearce 1998). Environmental economics is the subset of economics that is concerned with the efficient allocation of environmental resources (ELC 2007). Ecological economics in its part refers to an economic system that is consistent with and honors the basic principles of ecology. In a broader sense, it refers to economic theory and practice that see the economy as operating within, rather than dominating, the spheres of nature, society, and culture (Capra and Jakobsen 2017).

Ecological sustainability has recently risen to prominence as a solution to serious environmental and social problems. With the growing world population and the increasing use of natural environments, the deterioration of environment makes economic development unsustainable. The signs are looming, such as the greenhouse effect and biodiversity loss due to the pollution of the air, water, and soil. Ecological sustainability is focused on protection and restoration of the integrity of the Earth’s ecological systems (Bosselmann 2017) for maintaining their essential functions and processes and retaining their biodiversity in full measure over the long term (BusinessDictionary 2018b). It can be seen as a development that provides the necessary environmental conditions which enable life on a certain level of well-being for present and future generations (Lele 1991). It is also a holistic view which stresses that sustainable development requires environmental protection and which is placed in a global ecological, socioeconomic, and political context (Sharpley 2000).

Ecological sustainability has three milestones: eco-efficiency, eco-equity, and eco-effectiveness (Dyllick and Hockerts 2002) (Table 2). The concept of eco-efficiency can be traced back to the 1970s as the concept of “environmental efficiency” (Freeman et al. 1973). In 1990, Schaltegger and Sturm introduced eco-efficiency as a “business link to sustainable development.” Later, it was popularized by the WBCSD (World Business Council for Sustainable Development)

Strong Sustainability, Table 2 The milestones and focuses of ecological sustainability (Brooke 2000; Dyllick and Hockerts 2002; ESCAP 2009; Gray and Bebbington 2000; UN 2009)

Milestones	Focuses
Eco-efficiency	Efficient economic activity with regard to nature’s goods and services Fundamental changes in the way societies produce and consume resources
Eco-equity	The equal rights of all peoples to environmental resources Social responsibility of the current generation for the future generations
Eco-effectiveness	Solutions for ecological problems A shift of mindset and transformation of business models

for the business sector in the course of UNCED (United Nations Conference on Environment and Development) in 1992 (UN 1992). In 2009, ESCAP (United Nations Economic and Social Commission for Asia and Pacific) defined eco-efficiency as a key element for promoting fundamental changes in the way societies produce and consume resources and thus for measuring progress in green growth (ESCAP 2009). Eco-efficiency plays an important role in expressing how efficient economic activity is with regard to nature’s goods and services (UN 2009).

Eco-equity lies at the nexus of the relationship between business and society (Dyllick and Hockerts 2002). It is an environment-centered principle and refers to the “equity between peoples and generations and, in particular, the equal rights of all peoples to environmental resources” (Gray and Bebbington 2000, p. 3). Eco-equity focuses on social responsibility of the current generation for the future generations. To cultivate eco-equity, the traditional views of the human-nature relationship, such as technocentrism and anthropocentrism, should be replaced with biocentrism and ecocentrism (cf. Daly and Cobb 1994). Biocentrism recognizes Earth’s organisms, ecocentrism in its part Earth’s interactive living and nonliving systems as central in importance (Barnard 2006; Piccolo 2017). Education

provides an excellent means for this realization. The overall goal of the UN Decade of Education for Sustainable Development (2005–2014) was to integrate the principles, values, and practices of sustainable development into all aspects of education and learning (UNESCO 2009).

Eco-effectiveness aims beyond merely reducing negative environmental impact by ending ecological degradation. Its ultimate goal is environmental protection. It aims to stop contamination and depletion by directing individual and organizational attention to the underlying and fundamental factors of environmental problems and to make possible long-term prosperity through a fundamental redesign of the system. In essence, efficiency is about “doing things right,” while effectiveness is about “doing the right thing.” Seeking an ultimate solution for ecological problems, eco-effectiveness requires a shift of mindset and transformation of business models (Brooke 2000).

Ecocentric sustainability represents very strong sustainability position or deep ecology (Turner 1993). The core idea in very strong sustainability position is that nature has intrinsic value which means that it is valuable in its own right. Advocates of deep ecology have extreme preservationist attitude to nature (Davies 2013). They argue for a particular type of non-substitutability based on an ethical rejection of the trade-off between produced and natural capital (Turner 2000). It stresses steady-state economic system based on thermodynamic limits and constraints and minimization of matter and energy throughput (Davies 2013; Turner 1993).

Deep ecology is based on eight principles or statements:

1. The well-being and flourishing of human and nonhuman life on Earth have value in themselves. These values are independent of the usefulness of the nonhuman world for human purposes.
2. Richness and diversity of life forms contribute to the realization of these values and are also values in themselves.
3. Humans have no right to reduce this richness and diversity except to satisfy vital needs.

4. The flourishing of human life and cultures is compatible with a substantially smaller population. The flourishing of nonhuman life requires a smaller human population.
5. Present human interference with the nonhuman world is excessive, and the situation is rapidly worsening.
6. Policies must therefore be changed. These policies affect basic economic, technological, and ideological structures. The resulting state of affairs will be deeply different from the present.
7. The ideological change will be mainly that of appreciating life quality rather than adhering to an increasingly higher standard of living.
8. Those who subscribe to the foregoing points have an obligation directly or indirectly to try to implement the necessary changes (Naess 1986).

Advocates of very strong sustainability position argue that when culture of a system changes, also external as well as internal elements of the system are altered (Davies 2013). Culture is here understood as a conceptual scheme encoding social behavior. It mediates human action including decisions on what and how to manage biological resources and transform ecosystems (Vayda 1983; Yengoyan 1986). “Cultural change” means radical change of human behavior to the nature and deeper connection with life, where humans are integral part of the environment and have to find a role in protecting the earth. This also stands as an environmental philosophy or social movement considering the religious and mystical undertones (Turner 2000).

Unfair distribution of resources within and between generations is a common problem to be solved in strong and very strong sustainability position (cf. Gladwin and Kennelly 1995). Teaching eco-responsible values and beliefs can raise awareness concerning it and other environmental problems. It requires both ecocentric ways of teaching and learning (Shoreman-Ouimet and Kopnina 2016) and also new ways of thinking including new economic models (Spash 2015) and broad scientific and

philosophical thinking (Callicott 2013; Steffen et al. 2015).

Summary

Weak and strong sustainability positions are often used concepts within the field of economics. Weak sustainability position implies a constant amount of resources over the time, while natural and produced capital are interchangeable. Strong sustainability position in its part has biocentric perspective and preservationist ideal. Based on it, a system is to be seen as one element which changes as a whole. Advocates of strong sustainability position recommend the precautionary principle and stresses that those options which may generate the worst outcomes and encompasses should be avoided. Strong sustainability position regards natural capital as providing some functions that are not substitutable by produced capital. Consequently, conservation of natural capital and the application of the safe-minimum standard are in the core of strong sustainable strategy. In ethical reasoning collective interests take over individual ones. Strong sustainability position represents deep green economy where no economic and population growth is allowed.

Advocates of strong sustainability position emphasize three milestones: eco-efficiency, eco-equity, and eco-effectiveness. Eco-efficiency is focused on economic activity with regard to nature's goods and services and stresses fundamental changes in the way societies produce and consume resources. In the core of eco-equity are the equal rights of all peoples to environmental resources and social responsibility of the current generation for the future generations. Eco-effectiveness again try to find solutions for ecological problems. It also has requirements concerning a shift of mindset and transformation of business models.

Very strong sustainability or deep ecology has ecocentric perspective. It has extreme preservationist ideal and stresses a "cultural" change. Based on bioethics, the advocates of very strong sustainability position emphasize

intrinsic value in nature thinking that nature is valuable in its own right. They also support the idea of very deep green economy that economy must be heavily regulated to minimize "resource-take."

Description

The basic idea of sufficiency has been around for centuries in religious and philosophical contexts: How much is enough for a good life? Today sufficiency is at the core of the debate on sustainable development (especially in rich countries). While eco-efficiency helps to buy time with “business as usual” (solve all problems created by technology by better technology), the core development problem is a cultural and moral one about limitations. Sufficiency is an individual decision about lifestyle and consumption patterns. Individuals reflect and may find that more income and more consumption do no longer contribute to increase their well-being. They might also check their values and find certain consumption patterns no longer compatible with the future of their grandchildren. The overall conclusion would be: “less is better.” Consciously consuming less (combined with less income and less payed work) could actually increase well-being (happiness). As the formation of consumer preferences is to a larger extent, a social process, peer groups (status), suppliers (advertisement), and government (infrastructure) play a vital role. Government provides the framework and institutions that make the individual sufficiency decisions hard to implement as they are basically designed in favor of increasing production and consumption (economic growth). Growth policy has to be replaced by sufficiency policy. The macroeconomic consequence could be secular

stagnation or a smaller GDP (degrowth). Sufficiency cannot provide an effective contribution to SD as long as there is no systematic and consistent government sufficiency policy which includes all relevant policy fields and instruments.

Introduction

The basic idea of sufficiency has been around for centuries in religious and philosophical contexts: How much is enough? (Skidelsky and Skidelsky 2012), how much is necessary for a good life? Economist from A. Smith to J. St. Mill and to J. M. Keynes addressed the issue and the perspectives of increasing wealth by providing more and more consumer goods. Another root of the sufficiency debate is the critique of “consumerism” (see Veblen 1899; Galbraith 1958).

The new context today is sustainable development (SD): What level of consumption is possible today (living generations) without ruining the natural foundations of life for future generations? Formulated as a moral question: How could the present generation fulfill their needs and enjoy life if this would be at the cost of future generations? Embedded in the SD debate, sufficiency has a cultural dimension; it is about a common shared vision of the good life and about the “future we want” (United Nations Conference on Sustainable Development 2012, sustainabledevelopment.un.org).

The question is no longer an abstract philosophical one as science provides more and more evidence on the impacts of our production and consumption patterns on future generations – with climate change as the most prominent example. Others include loss of biodiversity, pollution of oceans, soil, water, and air with waste and toxic substances, depletion of non-renewable resources. There is increasing awareness that the planet entered the “Anthropocene,” that is, human race is dominating the evolutionary process, and that mankind is living beyond “planetary boundaries”, that is, consuming the substance instead of living from the dividends. Responsible for overburdening the carrying capacity of the planet are primarily people in the rich nations (global north) – but in general

rich people throughout the world (the affluent billion). Sufficiency is primarily addressing this “elite.” With respect to poor countries, “sufficiency” has a quite different meaning and is addressing the increase of consumption to fulfill at least the basic needs.

With the SDGs and the Paris Agreement in 2015, the debate on (environmental) boundaries for economic development has made significant progress. Together with national implementation plans and national sustainable development strategies, the framework to discuss sufficiency is pretty clear. Political relevance and urgency increases with the insight that increasing eco-efficiency – as a quasi-automatic by-product of technological progress – alone will not solve SD problems. Sufficiency has a vital function (see ► [“De-growth”](#)).

Sufficiency addresses the question how many products and services consumers actually need (Princen 2003; Kurz and Zahrnt 2016; Potočník et al. 2018). Would less quantities and spending actually reduce consumers’ well-being (happiness, overall life satisfaction, utility)? Interwoven but conceptually different from the “less” is the “different” aspect: choosing different product (e.g., more fuel-efficient car). While most sufficiency debates cover both aspects, the challenge clearly is on the “less,” the “zero option.” More efficient (“smart”) solutions easily find acceptance – at least in market niches. The core sufficiency challenge to the (about 1 billion) rich all over the world with affluent lifestyles is: less mobility (less kilometers travelled), less energy demand (lower room temperature), less land consumption (smaller apartments). Sufficiency is not identical with “Verzicht” (abdication, self-deprivation) – which includes an element of (willingly) suffering, for example, in a religious context (and thus could be beneficial).

Sufficiency is a challenge for individual consumer behavior and it has significant macroeconomic implications. It is a challenge to the core idea of economic growth. Less consumer demand means less production, less investment, and a smaller GDP (see entries on ► [“De-growth”](#) and ► [“Postgrowth”](#)). It causes new economic adaptation and transition problems which are challenging for theory and for policy (Samadi 2017).

IPAT and SD: What Could Sufficiency Contribute?

Any environmental impact I can be decomposed into three factors which explain the overall effect (IPAT equation, see ► [“De-growth”](#); Kurz 2019):

$$I = I/GDP * GDP/person * persons$$

$$\text{Impact} = \text{Technology} * \text{Affluence} * \text{Population}$$

These three components illustrate the basic strategic options for addressing environmental problems:

- **I/GDP** stands for the **efficiency** of resource use, delinking GDP from impact by new “smart” technologies (see ► [“Rebound Effects of Eco-efficiency”](#)).
- **$GDP/person$** or per capita income is often used as an indicator for economic wealth. Less income (less consumption) means less impact. How much income and consumption is enough? This is the **sufficiency** question.
- **Persons**: increasing **population** on the planet will increase the (negative) impact on the environment. Population increase and population policy will not be addressed here. From a sufficiency perspective, the question would be “how many children are enough?” – with the perspectives of individual preferences and of macroeconomic implications (aging).

$GDP/person$ has been used as a proxy for standard of living and happiness H . The goal of economic policy has always been to increase peoples’ incomes. Now this would have to be reversed. This can also be illustrated by an extension of the IPAT equation:

$$I = I/GDP * GDP/H * H/person * persons$$

This equation could be called the **IPATH** equation. It highlights a fourth component for impact reduction: **GDP/H** , that is, the expenditure for market-based goods and services needed per “unit of happiness.” This has to decline. The challenge is to explore options for happiness (well-being, prosperity) which do not rely on (so much)

material goods. Happiness H per person does not have to decline. An implication is that with less expenditure for consumption less income is needed. This gives the opportunity of more leisure time (less paid work). In sum, a fundamental change in consumption patterns and lifestyles (in the rich countries), a “sufficiency revolution” that has to be triggered yet.

IPATH illustrates the “double delinking”:

- delinking type 1 is I/GDP , the efficiency revolution
- delinking type 2 is GDP/H , the sufficiency revolution

The efficiency revolution plays an important role in achieving SDGs. However, so far the revolution is only a modest one, not powerful enough to comply with SDGs like reduction of CO_2 -emissions (see entries on ► “De-growth” and ► “Post-growth”). Maybe, it is possible to stimulate higher rates of efficiency increase in the future. However, it would be irresponsible to rely on this option only. Nobody is able to predict whether it will be possible to close the gap (with eco-innovation policy). The existing gap has to be filled with sufficiency and sufficiency policy.

What could the sufficiency option contribute to SD in quantitative terms? An example which is focusing on CO_2 -emissions helps to illustrate the potential scope. If the following simplifying assumptions hold:

- The affluent billion of the world population emits 17 t CO_2 per capita p.a.
- The rest of the world population (6 billion people) emits 3 t CO_2 per capita p.a.
- The affluent billion succeeds in a 50% reduction of their consumption (and incomes) until 2050 – and as a consequence of their per capita CO_2 -emissions.

The result would then be that global CO_2 -emission would decline by 8.5 billion tons p.a., from 35 billion tons p.a. today to 26.5 billion p.a., that is, a 24% reduction of total global CO_2 -emissions. If reductions of 80–90% are necessary to avoid a global temperature increase of more than 2 °C (Paris Agreement) and if an efficiency factor

4 (= 75% reduction) is assumed, sufficiency could close the gap. If the efficiency effect is smaller, sufficiency is even more important. In this scenario, the 50% reduction of consumer spending is extremely ambitious and the question is what could make such an option attractive to the affluent?

Is Sufficiency Attractive?

The basic idea of any capitalist system is to keep people satisfied by permanently increasing the quantity and quality (innovation) of goods – combined with decent work for everyone to finance consumption. Under these conditions, the system works well and is stable. Only recently there is more attention for the question “how much is enough” (Skidelsky and Skidelsky 2012). Being trapped in the work-consumption-circle is no longer a generally shared vision and this type of “social contract” is losing attraction for wealthier nations and individuals. Mill (1848) and Keynes (1930) recognized this and emphasized the positive aspects of a “stationary state.” Today there is ample empirical evidence that beyond a certain level of income, further increase of income and consumption will not increase well-being and happiness (see Easterlin 1995; Frey 2008).

But could “less” really be an attractive perspective for a majority of people? A little bit less seems to be attractive – at least if the success of publications on “simplify your life” is accepted as an indicator. Doubtful is whether significantly less would find any public support. Would anyone join an initiative to reduce consumption expenditures by 1% every year over a period of 20 years (i. e., roughly 20% in total)? How many would subscribe to the idea “50 % less”?

Consumers’ awareness of SD challenges has increased, they are well-informed, transparency, and purchasing decisions are supported by all kinds of (green, fair) labels. But these “enlightened preferences” have little effect as people have learned to live with cognitive dissonance and companies invest heavily in advertisement to stabilize demand for their products, turning “unsaturable needs” from a textbook assumption into a reality. In fact, there is a (global)

homogenization of (western) lifestyles and popular culture (see Ritzer 1993) driven by communication technology and the urbanization trends. Children grow up more in virtual realities than in nature.

The competition-driven innovation system throws out “new” products every day, often just minor (incremental) changes and “fashions.” Innovation is celebrated without realizing the dark side of “creative destruction” (Schumpeter 1942), the premature obsolescence of perfectly functioning products (see Kurz 2015). Consumers are locked-in with the old products (stranded assets).

Today sufficiency is primarily an individual search process, testing new consumption patterns and exploring and finding new lifestyles (social innovation). Government policy is not supportive as it is focused on fostering the innovation and growth process, the increase of GDP/capita as the only relevant indicator for economic wealth. Nevertheless, there are tracks of sufficiency and the niche of LOHAS (lifestyle of health and sustainability) seems to expand. Established companies did spot the trend and integrate it in their advertisement, however not always in their strategies (see Joanes 2019). An outstanding example is the “don’t buy this jacket” campaign of the outdoor equipment provider Patagonia (see www.patagonia.com). New companies in the sharing economy have commercialized sufficiency ideas (sharing cars and rides, sharing apartments). Civil society organizations are organizing many projects to support less consumption (like repair cafés, urban gardening). The young generation is asking for work-life-balance and is willing to give up income in order to raise kids. Mobility patterns are changing, urban citizens own no car (don’t even have a driver license), flight shame is often mentioned. Vegetarian and vegan food is on the rise. New forms of living together are tested. So far, most of this has no significant overall effect: mobility is increasing (although smarter); average size of apartment increases (as number of single households increases), etc. In sum: There is change in niches, high creative potential, some “business cases” – and ample opportunity for more.

Macroeconomic Effects: Secular Stagnation

Sufficiency has consequences for other household decisions as well as on the macroeconomic level. A macroconsequence of a continuously declining private demand could be long-term economic stagnation (secular stagnation, see Summers 2016) or even decline (see ► “De-growth”). This depends also on the other components of demand: investment I, government spending G and trade balance (Ex-Im):

$$\text{GDP} = \text{C} + \text{I} + \text{G} + (\text{Ex} - \text{Im})$$

When consumer demand declines, investment will follow. With a declining GDP, tax revenues and hence government spending will decline (permanent deficit spending ruled out). Exports could compensate all this. Together with an expected decline of imports (closely related to economic activity), this would create a large surplus in the trade balance. Other countries would have to run a deficit – and will not accept this long-term.

Therefore, if sufficiency in lifestyles and consumer spending becomes more significant, the probability of secular stagnation increases. This conclusion follows not only from the demand factors but also from the supply-side restrictions (see ► “De-growth”). Sufficient lifestyles affect the demand-side and supply-side of the economy simultaneously. If individuals consume less, they need less income and hence could reduce worktime (enjoy more leisure time). If labor supply declines, various effects will compensate this: increasing wages, automatization, global supply chains. In some segments (with specific high qualifications), labor supply could become a bottleneck and restricting output (GDP growth). More leisure time could be invested in community projects and thus increase social capital, that is, increase the wealth of nations.

If secular stagnation is a realistic long-term perspective, the second interesting question is related to the adaption process, the transition from growth-oriented to low-growth or no-growth societies. How to make this a smooth adaption rather than a cumulative downward spiral? While scale is shrinking the process of structural

change continuous and might even accelerate (e.g., for the automobile industry). There is little knowledge and research on designing such a transition process (see ► “De-growth”).

Keynes’ (1930) optimistic vision was that within a century, average people could reduce working hours to 15 h per week. This forecast is based on

$$\text{GDP} = \text{GDP/hour} * \text{hours/worker} * \text{workers}$$

If labor productivity (GDP/hour) grows at 2% p.a. over 100 years, it would easily be possible to reduce labor time for a given number of workers producing a constant GDP to 15 h/worker. But why is everyone still working much longer (e.g., 35 h/week in Germany)? Obviously workers were not satisfied with their income (GDP) as of 1930. Most of the efficiency gains were thus used for higher incomes and consumption levels. And this is still the situation: productivity increase can be used for wage increases or for reduction of working hours. Only when workers are satisfied with their income levels, Keynes’ vision could unfold its full potential: More leisure time could make people happier.

Sufficiency Policy

Sufficiency is not only a challenge for individual decision making but also for political decision making on framework conditions which are always a determinant in consumers’ decision making. A government sufficiency policy could enable and incentivize consumers. However, no consistent concept has been formulated yet. It has to steer clear of paternalism and eco-dictatorship. It would be naïve to leave it to individuals alone to change their decisions without addressing the political framework conditions which influence these decisions. Good-intended moral behavior will finally surrender to hostile circumstances. The legal and institutional framework has to be favorable for moral decision making. Moreover, if consumers would have to include a complex, multidimensional goal system like the UN SDGs in their decision making, they would be

hopelessly overburdened. Complexity reduction and translation is necessary.

A holistic concept of sufficiency policy must include (almost) all fields of government policy, at least must check their relevance and the effectiveness of potential changes. Following the conventional list of economic policy instruments, important components of sufficiency policy are:

1. Information: Reduction of complexity by creating and supporting reliable labels (fair trade, FSC, etc.). Support for traditional consumer protection organization should be redirected to include sustainability issues. Results of behavioral economics on (irrational) consumer behavior provide new approaches (nudging).
2. Education: Consumer behavior and decision making is far away from the autonomous textbook individual. Preferences are formed as part of the industrial production process. Education could contribute to make individuals more independent from status and consumer goods and strengthen their personal capabilities.
3. Voluntary agreements: Companies often claim a pioneer role in sustainability and Corporate Social Responsibility (CSR) and could voluntarily do more beyond reporting, especially in their product policy (longevity vs. obsolescence).
4. Government spending: Internal processes, purchasing behavior, infrastructure investment (bike lanes and public transportation instead of highways) have to change. An extended social safety net (basic income) could back sufficient lifestyles.
5. Prices could be a simple indicator for sustainable consumption and change consumer decisions significantly – if only they would tell the (ecological and social) “truth”. Government can correct market prices by taxes and subsidies. Alternative are cap-and-trade systems.
6. Regulation (command and control) always seems to be the ultima ratio. However, this instrument has significant advantages as it relieves individuals from decision making, is fair (equal for everyone) and effective, for example, fuel-efficiency standards, phase-out of fossil car engines.

Summary and Perspectives

Sufficiency is one of the two core strategic options for achieving sustainable development goals. Political debate is dominated by the other one, the efficiency option: Use less resources per unit of output (GDP). If eco-efficiency increases, it is possible to delink economic growth and environmental impact (resource consumption). The success of this option depends crucially on eco-innovation in the business sector: If more eco-efficient production processes and more eco-friendly products are delivered (with only moderate price increases and combined with improved social and labor standards), SD is not bothering consumers too much. That such ambitious innovation processes could be accelerated is the hope of all concepts of “Green Growth.” Per capita income will continue to increase and the promise of modernization is intact.

Different from the efficiency revolution the sufficiency revolution is more challenging and has the potential of a cultural revolution, a fundamental change of society and economy. It is not just about eating a little bit less meat or less flying. Sufficiency is questioning the whole concept of “pursuit of happiness” by increasing the production and consumption of more goods. It is about breaking up the vicious circle of more needs, more income, more (alienated) work, more (compensating) consumption. Jonas (1979) formulated this as the duty to work against hedonistic consumerism – and increasing “flight shame” might be a first success. Refocusing the materialistic system and developing cultural perspectives beyond can rely on many sources – from Fromm (1976, to have or to be) to Illich (1973, self-sufficiency, conviviality). The open question is whether developed nations will be able to achieve the huge cultural accomplishment to voluntarily impose limitations on the use of natural resources. This is not impossible as has been demonstrated related to the factor labor (child work, slave work) and the Paris Agreement (2015) could be another success story.

As a consequence of the poor results of eco-efficiency strategies, the sufficiency strategy needs much more attention. It addresses the

core of the sustainability idea: After a period of unprecedented increase of material wealth (GDP), the cost and benefits of additional income and consumption have to be re-evaluated. More sophisticated technological solutions (eco-efficiency) can help to moderate some conflicts and to follow the growth path for a while (buy time) but eventually the challenge of refocusing individual lives and social consumption patterns cannot be neglected (as economists like Mill and Keynes have already pointed out). Instead of postponing sufficiency, a more proactive attitude is necessary.

Sufficiency will have deep impacts on the business sector and – on a global scale – on consumption patterns and lifestyles also in emerging economies. What is possible is already demonstrated in many innovative projects (including car-sharing, urban gardening, repair coffees) and more creative solutions will emerge, all demonstrating that sufficient lifestyles are not equal to abdication and are not a barrier but a promising way to the pursuit of happiness.

Sufficiency is about change of individual consumption patterns but it is also about sufficiency policy. Without a systematic and consistent government policy, sufficiency will have little effect. Research on and implementation of sufficiency policy is the next crucial step for SD.

University of Urbino Carlo Bo, Urbino, Italy

Synonyms

Authentic CSR; Explicit CSR; Formal CSR; Implicit CSR; Informal CSR; Opportunistic CSR

Definition

CSR (corporate social responsibility) can be either extrinsically motivated or based on intrinsic reasons (Looser and Wehrmeyer 2015). Extrinsic motivations are often instrumentally driven since they are aimed at increasing the shareholder value, while intrinsic motivations arise from the idealistic conviction that acting in a certain way is the right thing to do. Extrinsic CSR is formalized and oriented towards external recognition and increasing legitimacy by improving company's image, legitimization, and market share. This approach often underpins the “green-washing” phenomena (Castelló and Lozano 2011; Gray et al. 2014; Mahoney et al. 2013; Visser 2011).

By contrast, intrinsic CSR is consistent with responsible practices triggered by a vision promoted by the entrepreneur and/or the top management (Jenkins 2006; Lamont 2002) and shared within the organization, thus making CSR a moral duty (Campbell 2007; Del Baldo 2013; Looser and Wehrmeyer 2015). This approach – diffused among small and medium-sized enterprises (SMEs) – is often not based on formalized tools and structured CSR policies and it usually rests on an ethical construct that triggers personal and authentic-driven relationships with stakeholders (Graafland and Van de Ven 2006).

S

Sufficiency Policy

► Sufficiency

Introduction

Within the lines of thought that nurture the debate on CSR, there are divergent positions and

assumptions about the motivations that lead firms to embrace CSR actions and strategies. Literature points out that motivations can be tied to both opportunistic and idealistic reasons.

The former, assume the existence of a win-win relationship between CSR and financial success. Companies can gain several benefits from a formalized strategic engagement in CSR, such as through investor relations management, stakeholder engagement, energy-saving programs, or environmentally practices that contribute at reducing costs and risks. CSR increases legitimacy and improves a company's reputation. It allows organizations differentiate from competitors and increase profit and market share (Weber 2008). In other words, extrinsic CSR is conceived by managers as a market-driven opportunities. Coherently, it manifests in the adoption of certified management systems and accountability tools, such as social report, sustainability report or integrated report (Cassimon et al. 2015) because it is aimed at external recognition (Matten and Moon 2008) and competitive goals attainment.

The latter (idealistic reasons) underpin the behavior of companies that are characterized by a responsible conduct and a purpose-driven business culture, thus making CSR a moral duty (Fifka 2012; Story and Neves 2015). Although literature emphasizes CSR integration within larger corporations, CSR also plays a pivotal role in SMEs despite being less institutionalized. The moral activity is the stronger motive for CSR because it represents the will to obey a certain moral norm as it is desirable for itself (Looser 2019). Intrinsic CSR manifests in fact in the form of codified norms, rules, and unwritten laws (Fassin 2008) and can be synthesized as "walking to talk" (first CSR practices, then communication). Some authors argue that the moral motive is more important within CSR than the economic view and that intrinsic motivation triggers an authentic-led involvement in CSR (Graafland and van de Ven 2006; Story and Neves 2015; Williams and Schaefer 2013) and generates a socio-competitive creativity (Molteni 2009).

Key Issues

Explicit CSR is triggered by individualism and incentivizing responsive actors that are rooted in liberal market economies. In these contexts, globalization, deregulation, and highly competitive markets create the need for explicitly formalize and communicate. Explicit approaches are required in response to stakeholder pressure (such as consumers and the civil society, among others). In other words, explicit CSR is not conceived as a voluntary and deliberate corporate decision but rather as a reaction to or reflection of society's demands (Looser 2019). Both mandatory and voluntary programs and strategies implemented by corporations usually combine social with business value. CSR as "business case" rests in fact on the assumed positive relationship between corporate social activities and financial performance and the aim to maximize profit. It often involves partnerships with governmental and nongovernmental organizations aimed at increasing legitimacy by improving the company's image (Matten and Moon 2008).

By contrast, implicit CSR is mainly determined by values and norms nurtured by personal relationships and collaborative networks involving companies and stakeholders. It is rarely explicitly described as CSR, rather it underpins codified and unwritten rules. Having an implicit approach to CSR is seen as "moral activity" and a "natural" and normal behavior to do business.

Extrinsic CSR is diffused among large companies while SMEs are more often intrinsically motivated and operationalize their values in the absence of an explicit agenda. In a nutshell, instead of formally report about CSR, SMEs "walk the talk." SMEs rely on long-standing informal networks – triggered by entrepreneurs who are driven by values derived from their personal, familial, and local community – rather than on formal policies (Aragón Amonarriz and Iturrioz Landart 2016; Del Baldo 2012, 2013; Fifka 2012; Gunilla 2014; Murillo and Vallentin 2012; Spence and Schmidpeter 2003). Consequently, CSR implementation is often related to moral commitment rather than to profit-

maximization because the entrepreneur is rarely motivated by purely economic factors. In this context, CSR emerges from the value-set shared by the entrepreneur and his/her collaborators. More often, he/she is characterized by a strong identification with the organization (organizational commitment) and is given personal power linked to authority, as is typical stewardship relationships. Values and personal commitment about proper conduct of business are the most important motivators within SMEs whose success relies on trust, reputation, and long-term partnerships. Therefore, the concept of CSR rests on ethical concerns, which most of SMEs fill by their family long-lasting values.

Some studies point out that intrinsic motives generate a more authentic involvement (while extrinsic one are often perceived as misleading) and that actual CSR performance is often more strongly correlated with the intrinsic/moral view than with the extrinsic/financial view (Graafland and Mazereeuw-Van der Duijn Schouten 2012).

Drawing from the entrepreneur's ethic-driven orientation (Jenkins 2006), several types of SMEs' approach to CSR have been pointed out, such as the ideal-based companies (Molteni 2009) and the territorial companies (Del Baldo 2010). Since ethics and religious beliefs are among the most consistent reasons behind socially responsible approaches (Looser 2019), a moral orientation underpinning CSR (Hoivik von Weltzien and Melé 2009) has been marked in "spiritual enterprises" (Capaldi 2013; Malloch 2009) and economy of communion companies (Del Baldo and Baldarelli 2015).

At the same time, literature highlights a limited degree of commitment of SMEs to formalized CSR actions. Many of the voluntary activities carried out are in fact scarcely systematic, and they have low visibility outside the company. This approach at the scientific level is known as the phenomenon of "sunken CSR" (Matten and Moon 2004; Russo and Tencati 2009). However, it should be further investigated and additional empirical research can shed new light on the specificities of SMEs in approaching and

communicating CSR, as well as on the specific factors that hinder or facilitate CSR diffusion among SMEs (Jenkins 2004; Spence et al. 2004).

Future Directions

Several authors point out the role of CSR in enhancing financial performance (Weber 2008) and increase company reputation, while others argue that CSR is a moral duty resting on a "social contract" (Campbell 2007) that supports responsible business behaviors (Arend 2013; Arjaliès and Mundy 2013). Moreover, some authors argue that in Europe extrinsic CSR is tied to large and public companies (Fifka 2012; Spence et al. 2003) while SMEs are mainly intrinsically motivated and do not adopt formal CSR policies (Looser and Wehrmeyer 2015; Matten and Moon 2008). By contrast, companies from the USA primarily evolve explicit CSR based on their liberal market economy (Matten and Moon 2007). Several studies point out that CSR can vary over countries in its explicit/implicit construct according to different societal, cultural, political, and economic systems. However, other studies point out that SMEs manifest an implicit CSR orientation independently from the market economies they are embedded in (Looser 2019). Increasing formalization represents a concern for SMEs giving rise to the prejudice that informal CSR is worth less due to a lack of instruments to communicate the factual orientation (Looser 2019). Hence, closer scrutiny is needed to differentiate between explicit/strategic and implicit/non-strategic approaches.

Summary

Despite the increased recognition and emphasis attributed to CSR, numerous problems and scandals involving large corporations continue to emerge. This contradiction nurtures a growing interest in intrinsic CSR rooted in ethical concerns spread among the company's culture. While larger

companies have to consider the expectations of shareholders and multiple stakeholders, SMEs do not need to be accountable to stakeholders through a systematic and formalized approach grounded on the adoption of sustainability reports useful to assess and demonstrate their CSR performance. However, the difference between extrinsic and intrinsic CSR is often very difficult (first) to understand and (second) to bridge and some authors advocate that the extrinsic and the intrinsic motive for CSR could evolve and be integrated.

Definition

A growing number of manufacturing companies adopt a strategy focusing on their core competencies while outsourcing the non-core activities from their suppliers as a response to stiff competition, ever-changing technology, and shortened product life cycle. Also, concurrently, they are required to comply with regional, national, and international laws and regulations in order to remain in business because environmental and social issues cross the regulatory boundaries from companies to customers, suppliers, competitors, and the community. In this regard, supplier management practices which have been principally studied within the context of sustainable supply chain management, are deemed a prerequisite for ensuring compliance of suppliers with buyer companies’ corporate sustainability standards (CSS). Self-assessment, as one of the most widely used supplier management practice, seeks to identify and influence on the areas which entail

improvement endeavors, while recognizing and maintaining the existing practices. In 1994, European Foundation for Quality Management (EFQM) defined the self-assessment as “a comprehensive, systematic and regular review of an organization’s activities and results referenced against a model of business excellence.” The underlying rationale for conducting a self-assessment questionnaire is the necessity to determine the readiness of the supplier to adopt sustainable practices. Therefore, in line with the supplier self-assessment, the performance of sustainable supply chain could be improved. To address the sustainability issues among suppliers, a self-assessment questionnaire can either be conducted by the buyer itself such as Wafios and EnQuest (Wafios 2019; EnQuest 2019) or by collaborative platforms, industrial partnerships, and industrial coalitions, such as Sedex, Responsible Business Alliance, and DRIVE Sustainability (Drive Sustainability 2019; Responsible Business Alliance 2019b).

Introduction

As a result of stiff competition, ever-changing technology, and shortened product life cycle, manufacturing companies have adopted a strategy in which they focus on their core competencies while outsourcing the non-core activities from their suppliers (Lam et al. 2007). At the same time, they are also required to comply with regional, national, and international laws and regulations in order to remain in business because environmental and social issues cross the regulatory boundaries from companies to customers, suppliers, competitors, and the community (Trowbridge 2006). In this regard, supplier management practices which have been principally studied within the context of sustainable supply chain management are considered a prerequisite for ensuring compliance of suppliers with buyer companies’ CSS (Grimm et al. 2016). The most commonly used ones – including product content requirements, product content restrictions, product content labeling or disclosure, *supplier questionnaires*, supplier environmental management systems, supplier compliance auditing, product

stewardship, education and collaboration, and industrial ecology – give rise to a sustained competitive advantage to companies that incorporate them into their supply chains. They can thus reduce social and environmental impact and foster sustainable development (Hamner 2006).

Supplier Management Practices

Supplier assessment/evaluation and supplier collaboration are the two dimensions of the supplier management practices. The foremost supplier assessment elements which are requesting certifications from suppliers, supplier evaluation and selection in line with the defined sustainability criteria, supplier monitoring and auditing programs, and supplier self-assessment questionnaire as shown in Fig. 1, are used to manage suppliers to ensure their compliance with CSS. Starting with the third party supplier certifications such as ISO 9000, ISO14000, and SA 8000 standard, the relevant certifications prove that suppliers meet the certain minimum requirements. Thus, this pre-selection process enables the buyer to externally verify its suppliers and obtain short-list of them. Suppliers can be further evaluated in accordance with the selected sustainability criteria during supplier selection processes which both allow for choosing more capable suppliers and eliminating the risk of any non-compliance that might elicit in later periods. Based on the requested corporate sustainability standards, it is also possible to use social and environmental audits with the purpose of assessing actual sustainability performance of suppliers. Concerning the auditing, the process could be carried out with the integration of various organizations such as the buyer itself, non-governmental organizations (NGOs), or independent auditing companies. In other words, the auditing process can be conducted by the first-party audits in which the supplier itself handles its self-assessment; by the second-party audits which incorporates into the buying company or the buyer’s buyer; and by the third-party audits with the participation of an independent, accredited auditing company. Despite being a more informal type of auditing, supplier monitoring

Supplier Self-Assessment Questionnaire, Fig. 1 Supplier self-assessment questionnaire as a supplier assessment practice. (Source: adapted from the study of Grimm et al. (2016))

continuously observes suppliers’ performance. In the assessment phase, the buyer can request its suppliers to fill out the self-assessment questionnaire in order to be sure that they comprehend its expectations. In accordance with the assessment results, feedback is given to the suppliers (Grimm et al. 2016).

The Importance of Self-Assessment in the Supplier Management

Self-assessment, as an imperative tool for sustained business improvement, seeks to identify and influence on the areas which entail improvement efforts, while recognizing and maintaining the existing practices. Based on the definition of EFQM, self-assessment could be considered as “a comprehensive, systematic and regular review of an organization’s activities and results referenced against a model of business excellence.” The process of the self-assessment enables the

organization to discriminate its strengths, identify areas in which improvements can be achieved, and eventuate in planned improvement actions that are monitored for progress. The widespread use of quality standards and awards including the ISO9000, Malcolm Baldrige National Quality Award (MBNQA), the European Quality Award (EQA), and the Deming Prize has contributed to the increasing popularity of self-assessment which has been utilized to measure business performance. Relatedly, contribution of the self-assessment tool is twofold. Firstly, it can certainly facilitate the continuous improvement across supply chains, and secondly, it gathers different kinds of data, standards, and certifications and serves as a benchmarking platform, such as an industry coalition. In line with the assessment results, each member of the benchmarking organization can therefore identify its weakness and strength in comparison with the industrial average, and then develop an agenda for further improvement (Lam et al. 2007). To address the sustainability practices

among suppliers, a self-assessment questionnaire can either be conducted by the buyer itself such as Wafios and EnQuest (Wafios, 2019; EnQuest, 2019) or by collaborative platforms, industrial partnerships, and industrial coalitions such as Sedex, Responsible Business Alliance, and DRIVE Sustainability (Drive Sustainability, 2019; Responsible Business Alliance, 2019b).

The underlying reason for using several supplier assessment practices, in particular *supplier self-assessment questionnaire*, is the necessity to determine the readiness of the supplier to adopt sustainable practices. Indeed, the performance of sustainable supply chain could be improved by developing sustainability standards and assessing suppliers on those standards. In doing so, buyer companies continually review outcomes of supplier performance on each sustainability dimension. Companies which integrate environmental and social targets in their sustainable supply chain policies are putting pressure on their suppliers to adopt sustainable practices (Kumar and Rahman 2016).

Illuminating Examples on the Supplier Self-Assessment Questionnaires

There have been ample examples of supplier self-assessment questionnaires which have been conducted thus far. International Flavors and Fragrances Inc. (IFF), for instance, has employed Supplier Ethical Data Exchange (Sedex), a global membership organization with its more than 50,000 members in over 150 countries enables its members to manage their sustainable performance. The Sedex Self-Assessment Questionnaire which is one of the key tools used by the Sedex members in order to inform their responsible sourcing programs collects data across four key pillars including labor standards, health and safety, environment, and business ethic. In detail, although Sedex does not have its own code and determine a policy, its self-assessment questionnaire is based on the following codes: ETI Base Code: 2014 (Ethical Trading Initiative), SA8000:2014 – Social Accountability (SAI – Social Accountability International), ISO 14001: 2015 – Environment Management System

(International Organization for Standardization) and OHSAS 18001 occupational health and safety management system (Occupational Health & Safety Advisory Services) (Sedex 2019). In 2011, due to its doubling the number of suppliers, IFF requested its major suppliers to register with Sedex and asked them to fill out the Sedex self-assessment questionnaire in order to identify potential sustainability issues (Watson 2013).

In a similar vein, the myriad UK retailers including Marks & Spencer have experienced the mobile technology at which they monitor working conditions of suppliers and sub-suppliers by becoming a member of Sedex (Balch 2016). In fact, Marks & Spencer as a founding member, participating company, and member of the Board, has been involved in Sedex since 2004 and aims at driving continuous improvement of working and environmental conditions in global supply chains (Marks & Spencer 2019). By way of an example, M&S Foods works with Sedex as an industry ethical trade database and SMETA as an industry audit protocol in order to set a common standard and eliminate ethical audit duplications. In accordance with the process, all suppliers which are registered on Sedex and linked to M&S Foods must complete all sections of the Sedex self-assessment questionnaire in full. The buyer also monitors completion of the questionnaire (Marks & Spencer 2016).

The last but not the least instantiation, the Responsible Business Alliance (RBA), formerly known as the Electronic Industry Citizenship Coalition (EICC), was founded in 2004 by a group of leading electronics companies. Nowadays, RBA member companies that operate in electronics, retail, auto, and toy sectors, including Apple Inc., Facebook, IBM Corporation, and so on, are held accountable for using a range of training and assessment tools within the scope of a common code of conduct. The aforesaid training and assessment tools such as the RBA Self-Assessment Questionnaire (see the references to view a sample) enables its members to continually improve in the social, environmental, and ethical responsibility of their supply chains, while simultaneously strengthening the rights and well-being of workers and communities (Responsible Business Alliance 2019a). On the other hand, from a

supplier's perspective, the self-assessment questionnaire designed online allows for sharing the data with multiple customers, in particular those who have similar social and environmental compliance targets and thus facilitate meeting the standards (Gunther 2014).

Summary

To recapitulate briefly, instead of the supplier self-declaration of compliance, sustainable supplier management must be based on standards and include effective identification, assessment, monitoring measures, and compliance incentive systems (Foerstl et al. 2010). To this end, sustainable supplier management practices which are either performed by the buyer companies themselves or supported by strategic business partners are composed of both "assessment" such as supplier questionnaires, audits, site-visits, and "collaboration," including corrective action plans, workshops, and training. However, in comparison with collaboration, by virtue of their more unidirectional focus, supplier assessment practices are described by merely collecting information and thus evaluating suppliers' sustainability performance in this regard (Grimm et al. 2016).

Definition

A *Supply Chain* covers all the activities to create a product or a service from raw material supplier to final customer. As such, a supply chain consists of several companies working together to generate value and to achieve competitive advantage. More specifically a supply chain contains the material and information flow between different entities. Therefore, a supply chain typically describes the logistical processes linking the different companies such as transportation, warehousing, supply, and demand planning.

Introduction

Every company is part of at least one supply chain. Usually a company is part of several supply chains or a supply network. Supply chains get more complex when companies focus on core capabilities and outsource the rest to suppliers as well as when companies serve international markets, offshore some of their activities, and built global supply chains. Thus, in a globalized economy with a distinct supplier landscape, supply chains and their management gain in importance.

The scientific literature offers different definitions for the term supply chain, but definitions of major players such as the Council for Supply Chain Management Professionals (CSCMP 2013) or renowned textbooks (see, e.g., Chopra and Meindl 2016; Jacoby 2009; Simchi-Levi et al. 2007) typically include the following key aspects: The supply chain ranges from raw material supplier to final customer meaning it covers the whole way of a product or service. The supply chain includes both material and information flow (and sometimes also cash flows as compensatory payments between companies to share gains of a measure in a fair way). The supply chain focuses on logistical aspects to generate value for the customer and competitive advantage for the companies involved.

Stage View of Supply Chains

A supply chain is composed of different stages or echelons. These stages describe the way of the product from raw material supplier to final customer. Thus, one way to display a supply chain is to show the sequence of different partners involved in making the supply chain happen (see Fig. 1). Typical stages are – starting from point of origin – raw material or component suppliers, manufacturers, distributors or wholesalers,

Supply Chain,
Fig. 1 Supply Chain
Stages (Chopra and Meindl
2016)

Supply Chain, Fig. 2 SCOR model (APICS 2017; Zhou et al. 2011)

retailers, and customers/consumers (see e.g., Chopra and Meindl 2016). The type and number of stages depends on the type of product and supply chain. One important difference is between direct or indirect distribution of a product (e.g., direct sales versus retailing). As a company is typically a part of several supply chains and there are several players on each stage of a supply chain, the supply chain can also be displayed as an intertwined supply network to do justice to this aspect. Often, however, a simple picture of a linear supply chain is chosen for the sake of simplicity.

Process View of Supply Chains

A supply chain can be divided into different functional processes. This view of a supply chain typically focuses on one company in a supply chain and its links with other companies. The macroprocesses of a company are Supplier Relationship Management (SRM) describing the supply side of a company, Internal Supply Chain Management containing all internal processes of the company, and Customer Relationship Management (CRM) describing the demand or distribution side of a company (Chopra and Meindl 2016). Typical logistical processes of a company described in the literature are procurement, production, distribution, and reverse logistics. These processes are often used for displaying the process view of a supply chain (Deckert 2015).

A reference model for the process view of a supply chain is the Supply Chain Operations

Reference (SCOR) model (see Fig. 2) by the Supply Chain Council (SCC), now merged with APICS – The Association for Operations Management. The SCOR model contains four levels of processes. On the top level, the processes Plan (planning of the supply chain), Source (relationship with suppliers), Make (internal transformation process), Deliver (outbound logistics), and Return (reverse logistics) are distinguished (APICS 2017; Zhou et al. 2011). The processes Source, Make, Deliver, and Return correspond to the main logistical processes (see above). The subordinate levels contain different variants of the core processes adding accuracy and granularity. For example, on the second level the process Make is broken down into the sub-processes “Make-to-Stock,” “Make-to-Order,” and “Engineer-to-Order.” The newer versions of the model include the top level process Engage including support processes such as supply chain risk management or supply chain technology management (APICS 2017).

The SCOR model also offers performance metrics for the different levels of the model. The categories covered by these metrics are reliability, responsiveness, agility, cost and asset management efficiency (APICS 2017). There are empirical findings which show that the SCOR model is valid and the relationship of its processes is empirically supported (Zhou et al. 2011).

Issues of Supply Chains

The core issue of a supply chain is matching supply with demand. The main target is to

generate a supply chain surplus, i.e., the generated customer value minus supply chain cost, through cooperative measures. One aspect that affects the performance of a supply chain is the supply chain uncertainty, especially supply and demand uncertainty. Based on the uncertainty of the supply chain, a company has to find its strategic sweet spot between cost and service level. A strategic fit can be achieved if the desired responsiveness of a supply chain is achieved with adequate supply chain costs (Chopra and Meindl 2016; Simchi-Levi et al. 2007).

Related to the issue of matching supply with demand is a phenomenon called the “Bullwhip Effect” in which small changes of customer demand lead to disproportionately high and delayed fluctuations in the upstream processes. The upstream fluctuations can be five to ten times higher than actual customer demand (Jacoby 2009). The factors contributing to the bullwhip effect are demand forecasting, lead time, batch ordering, price fluctuations, and inflated orders, e.g., due to shortage gaming (Simchi-Levi et al. 2007). Measures for coordination in a supply chain such as aligning goals and incentives, improving supply chain visibility and operational performance, designing stabilizing pricing strategies, and building strategic partnerships can dampen the bullwhip effect (Chopra and Meindl 2016).

Summary and Outlook

The supply chain deals with all the activities to provide a product or a service from beginning (raw material) to end (use or consumption). The core issue of a supply chain is the matching of supply with demand and a focus on logistical aspects. A newer trend is to also focus on sustainability metrics to achieve a Sustainable Supply Chain. As companies are not only held responsible for their part in the supply chain, but also for parts covered by their supply chain partners, activities such as supplier rating gain in importance.

The SCOR model, e.g., now contains a special application called SustainableSCOR designed for

environmental accounting of a supply chain. The application is based on the standards for sustainability reporting by the Global Reporting Initiative (GRI) and contains metrics for materials used, energy consumed, water volume withdrawn, air emissions, as well as liquid and solid waste (APICS 2017).

Definition

The precise definition of supply chain management had already been subject to change as a result the use of computing, ICT, digital technologies, and their increasingly intrinsic physical impact. One such definition relates precisely to the blending and morphing of tangible and intangible elements of supply chains, i.e., the *digital/physical* dichotomy as it is incorrectly labeled. (Digital is physical, especially as far as electronic data transmission is concerned. This contributor had previously argued that a correct dichotomy may be defined differently. This, especially as the nature of technology innovation is likely to transform the physicality of tools used beyond recognition. Formulations such as “digital/material” or “tangible/intangible,” “electronic/corpuscular.”) “Supply chains can be described as a series of linked suppliers and customers, who can be termed links, actors or players” (Graham et al. 2004). (The authors went on to propose a networked approach to supply chains. Hence the sentence cited above ends with: “chains are commonly portrayed as simple linear processes.” While dynamically influencing media and entertainment, such network structures as postulated by Graham et al. (2004) (e.g., blockchain, in Dutra et al. 2018) are yet to develop full effectiveness in tangibly material form. NB blockchain is addressed below.) While many other, more detailed, and thorough formulations are of equally good use (e.g., the seminal work of

Mentzer et al. 2001), (For detailed definition by Mentzer et al. (2001: 18): “supply chain management is defined as the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purposes of improving the long-term performance of the individual companies and the supply chain as a whole.”) the one cited above was chosen for the relative elegance in the way in which it involves the transformation, blending, and merging of different forms of physicality and control. To further note, concerning the notions of transformation and control, transparency, together with resilience, is becoming a particularly important feature of supply chains, especially in sustainability contexts. This is explored, elaborated, and expanded in the sections below.

This definition and subject entry would need to depart somewhat from encyclopedic tradition: Due to the unprecedented transformative global crisis impacting health, trade, economy, safety, security, transportation, travel, and social conduct, more attention shall be given to current affairs than is the norm. (The term “the new normal” is already in widespread use across the world’s media and professional commentary. It remains to be seen how permanent “the new norm” may become. Ignoring such rapid change, however, would present a missed opportunity. Among other uses, encyclopedias do have historical value.)

A note on the supply chain impact of the COVID-19 global pandemic – also addressed below: While major crises do tend to cause remarkable tremors in field practice, it remains to be seen how lasting their effects may be. On the other hand, seemingly lateral developments – such as the invention of the printing press or that of the Internet – may cause far-reaching and considerable transformations less anticipated by analysts, practitioners, and others in their own current temporal contexts. It is a thankless task to assess the impact of contemporary events; nonetheless, an economic quake of the size of a global pandemic should not be ignored, especially in such conditions as those reported.

To follow a conventional approach to supply chain management, a succinct description may be as follows: *The management of product control and value-adding delivery (service) processes commanding all steps from production to consumption*. Such process management is centered on design, collaboration, and responsiveness; it involves logistics, inventory, stock control, and increasingly necessary automation. As is further elaborated in sustainability contexts, risk plays a major role, as do the strategy and organizational culture of companies involved.

Industry reports at a time of crisis happen to support the above. The value of established approaches is in that they tend to encompass follow-ups, provided of course (1) they have been correctly postulated in the first place and that (2) there were no major paradigm shifts that may have proven a latter explanation more encompassing than its antecedent (as is sometimes the case in science).

Overview

The subject of supply chain management, primarily contingent on recognition of technology-dependent and process-driven practice was first informed by would-be scientific means utilized in the fields of strategy, tactical operations, and logistics. (Strategic management texts informed by mathematics, applications of science for industry, economics, resource management, etc. have originally informed supply chain management theory (e.g., Ansoff 1965).) Such strategic operational practice was subsequently assessed, informed, and enhanced by means of theory, initially in the process- and statistics-influenced and hypothesis-defined science aspects of organizational performance. The processual schools of strategy in particular had at the time been defined instrumental and so by means-to-ends principles. As such, the approach would not have had notable critical components, (The influential work of Porter's competitive advantage (1985) employs considerably utilitarian concepts.) which would later emerge to make an impact on both theory and practice. As the significance of stakeholder

relations and those of the social impact of business activity and of corporate behavior gained broader recognition, supply chains were consequently addressed by means of sustainability conceptualization. Carter and Rogers (2008) are among the authors that worked to critically summarize and redefine supply chain management within the context of sustainability. This work proves of present value in the global context explored further, especially as its (i) comprehensive and (ii) conservative approach addresses sustainable supply chains in their risk-related and economic sustainability aspects. The focus on feasibility and functionality properties is visibly required.

In their highly impactful analysis, Carter and Rogers criticize much of the sustainability discourse (The subject field may be understood with root reference to Club of Rome imperatives (e.g. Oelze et al. 2018).) especially in the context of supply chains of the time in that it fails "to explicitly include what Carroll (1979) refers to as an organization's economic responsibility" (2008: 361). Such insight and critique are of particular value to this entry, given the timing and impact of events at the focus of change. Further, the authors called for a more consistent use of the term *sustainability* across literature and the industry, advocating for greater presence of economic and risk factors across the field. As shown in other, later treatises and across consequent practice, this assessment had made an impression. Some of the authors' other challenging questions include the correlation between environmentally conscious corporate strategies and profit-making ("Does it pay to be green?"). Drawing also on organizational aspects of engineering literature and finding them helpful, this comprehensive anthology invites for a more consistent and systematic use of sustainability in supply chain management texts. The entry also posits and attains the ambition to formulate theory-building for the purpose of sustainable supply chain management. Expanding on organizational sustainability, focused on "the natural environment, society, and economic performance," Carter and Rogers (2008: 364) further formulate the "triple bottom line." Citing theory as well as practice and expanding on the work of numerous important

analyses, the authors emphasize the importance of *interrelationships among risk management, transparency, (organizational) culture, and strategy*.

An integrative wide-ranging formulation of *sustainable supply chain management* (SSCM) is as follows:

as the strategic, transparent integration and achievement of an organization's social, environmental, and economic goals in the systemic coordination of key interorganizational business processes for improving the long-term economic performance of the individual company and its supply chains. Carter and Rogers (2008: 368)

Confronting/contrasting various sources of established thought in sustainability and supply chain literature, the authors propose that “goodness” at the intersection of environmental and social considerations is irresponsible toward both business goals and sustainability itself, were it not to involve economic factors. Thus, they arrive at a well-read nomenclature of economic advantages at the said intersection of environmental and social factors. Cited as: 1. *Cost savings due to reduced packaging waste*; 2. *Lowering labour costs – [as] Better working conditions can increase motivation and productivity*; 3. *Proactively shaping future regulation (...) leading to a difficult-to-replicate competitive advantage*; 4. *Reduced costs, shorter lead times, and better product quality [standards]*; 5. *Enhanced reputation (...) attractive to [stakeholders across the board]*.

The sheer impact of this work; its contrasting priorities against the backdrop current matters in the field and within the world economy at a time of unique crisis; and its systematic and detailed nature, all qualify it as a reference text. This, while providing due recognition to several relevant and influential works especially within the arenas of definition and particularly within the notion of commercialization, streamlining and strategizing of healthcare fundamental to the subject matter explored within the paradigmatic impact of COVID.

So that no singular text, however much influential, takes full precedence, the reader is invited to consult the following works and a

comprehensive bibliography slightly skewed toward the ongoing “transaction revolution” in supply and demand structures across the world. Indeed, worthy of attention among less known work is the paper by Syahrir and Vanany (2015) addressing *healthcare and disaster supply chains*. (Emergency operations fit for “epidemic attack through logistic operation for drugs” and “disruption problem of supply chain logistics for the availability of medical needs such as medicines in the health care facilities” (...). Also: “Problems that often arise in disaster relief operations are the lack of coordination and little knowledge of good logistics system[s]” (Syahrir and Vanany 2015: 6). Noting that “other research in the area of healthcare supply chain which consider abnormal situation[s] still needs to be done in the future” (2015: 4, 7).) Conditions that persist prior to the pandemic may be traced to, e.g., Byrnes (2004), Dobrzykowski et al. (2014), and Chakraborty et al. (2014). Also, bullwhip (positive feedback loop) effects in healthcare supply chains by Samuel et al. (2010); finance/resource strains and quality of care resolved by supply chain fine-tuning (Kwon et al. 2016). Closer to core subject matter in SSCM subjects range from the work of Glaeser and Kerr (2009) whose localized solutions may be of use in a post-COVID world; to more generic collaborative forms that may also fit a post-upheaval rethink (Hudnurkar et al. 2014); case particularities explored by Oelze et al. (2018); to extensive analysis of Gupta and Palsule-Desai (2011); quantitative modeling by Brandenburg et al. (2014); and many others.

As the above text represents a highly pragmatic approach analogous to established utilitarian notions of strategy, the sections below will observe a substantive rationality of changing principles.

Beyond Business Imperatives: Transparency, Control, and Consumer Preference Ethics

The notion of control: Accordingly, *transparency* in stakeholder terms, or *relative market power* – when centered on businesses – define the

important features of supply chains as addressed here. This, with particular attention to the environment – and health matters: especially the impact of [stakeholder] transparency and relative market power on health provision (and by it) in major crises and natural disasters, as has become rather evident at the time of writing [during the first wave of the COVID-19 pandemic]. Innovation plays a role in the enhancing of stakeholder positions, as well as improving business prospects. At times, the two are aligned owing to such technological innovation that is integrated into business models, customer relations, and marketing inherent in the supply structure. For instance, food (supply) businesses acting in transparently ethical manner: tracing an ethically sourced and environmentally friendly tuna catch (The Provenance Team 2020); Manuka honey (Steens Honey 2020); yoghurt (Kruschwitz 2014); or bananas and pineapples (Dole Earth 2011), customers and consumers tracking the entire process of production, procurement, and supply – identifying the very people and means involved and the places and locations of original product input.

However, concerning food production and supply – and food security in particular – the warnings that came with the global pandemic are likely to occupy the continued attention of both public and private decision-makers across the world's stakeholder spectrum (e.g., S&P Global 2020). More troublingly, Baker McKenzie reported a 0% global growth for 2020, a record worse than the 2008 crisis analyzing a likely impact on supply chains of multiple sectors. The sections below address what may be a lasting transformation of all trade with unprecedented worldwide impact.

Disruption, Risk, and Global Rethink: A Case Concerning Noticeably Vital Contemporaneous Events

The COVID pandemic may prove to be the tipping point of irreversible transformation of supply

chains (e.g., Kilpatrick 2020). This entry will aim to incorporate analytical and factual matters relating to the impact of the COVID pandemic. This, with the particular understanding that supply chain management may undergo considerable, and likely lasting transformation in its wake. Such transformation may come as a result of this event (or process) unprecedented in terms of many aspects of the economy of an interdependent world. Pandemics did occur in many past occasions; however, the world's economy, business, and trade were never as integrated, interdependent, data-driven, and globalized as they are in the early twenty-first century. The impact of COVID on healthcare supply chains will also be addressed below, e.g., Ranney et al. (2020).

As the COVID impact is proving transformative in a number of unprecedented ways (Shih 2020), the direction and means of physical and economic activity from basic to global are already reportedly affected. This is not limited to the re-stratification and destructive consolidation of the market and actual companies and sectors especially in transport. The disruptive effect of the pandemic may likely cement many cumulative effects of incremental changes and intermediate albeit regular technological leaps traceable to the increased need for automation and processing since the 1980s. Adding the impact of artificial intelligence, 4D printing, and Internet of Things (Mahto and Sniderman 2019) to this essential field of activity may radically alter the corporate landscape and methodology of industry practice, further empowering global ICT firms, i.e., those colloquially known as “[hi-]tech giants,” who appear to be the main winners in business amid the crisis (Amazon had reported highest increase in e-commerce growth related directly to the global pandemic. Particular increase of its previously lossmaking “Whole Foods” division in both revenue and profits reported despite initial concerns over self-imposed limitations on services due to COVID of resource stretch.) (Keyes 2020).

On the other hand, there is a rethink of global supply structures – and not without paradox,

given the conventional wisdom built over the decades of neoliberalism in global business. Namely, some industry analyses published at the time of writing (e.g., Holmes 2020; Mullin 2020, and others) point out that more conservatively designed supply chains based on higher sunk costs, lower reliance on outsourcing, and elements of local and regional analogue physicality (though integrated into the digital agility for planning and risk response) may prove robust and resilient to *force majeure* challenges such as the global lockdown. As the virus pandemic appears to be changing the very ways in which socioeconomic life and business operations are conducted worldwide, “more local supply can also enhance agility as companies can be more responsive to changes in local demand” (Frikkee 2020). Adding that while some cost may be passed on to the customer, more balanced business models and less haste in sustaining last-minute demand structures would see the rebuilding of national and regional supply infrastructures supported by AI, enhanced communication models, and automation created for worker safety and risk responsiveness. All this seems in line with sustainability priorities.

The most momentous aspect of that rethink is the World Economic Forum report – and toolkit for governments and businesses alike – focusing on blockchain technology as the means to “tackle supply chain failures exposed by COVID-19 and boost economic recovery” (May 2020).

Blockchain and Potential Developments from Food to Healthcare

Beyond, and predating the World Economic Forum reported plans, blockchain was being hailed as the ultimate solution to world’s economic woes and a solution for fair, transparent, and clean, decentralized method of ordering, paying, accounting for, buying and selling, supplying, and delivering goods and services by means of “smart contracts”. (As stated by Jessi

Baker, Provenance founder and CEO in her BBC Worldwide interview (The Provenance Team 2020).) Starting out as a fairly obscure even mysterious approach to software and trading in cryptocurrency circles, where all value is subject to agreement and complex, convoluted contractual exchange with data-value interaction collected, permanently saved and allocated at every transaction: Blockchain has been recently associated with some of the most ambitious plans for the rebooting of the world economy, supply of goods, services, and trade in the wake of the COVID crisis. Seldom do international bodies of such magnitude of influence such as World Economic Forum intervene so directly. It is therefore safe to assume that blockchain technology will emerge from its relative anonymity, earlier the preserve of the illustrious bitcoin and the focus of cryptocurrency entrepreneurs and enthusiasts. Should this be the case, it would form an about-turn as the very notion of decentralized cryptocurrencies was largely rebuffed in past instances by governments, central banks, and traditional financial services alike. Therefore, it is very likely that the new, reinvented utilization of blockchain would not be presented in the same form as in the past. Citing the World Economic Forum press release, dated 27 April 2020:

Resilience in supply chains depends on trust, transparency and integrity, which can be improved through the responsible deployment of blockchain technologies that offer a “shared truth”.

The current pandemic underscores the need for businesses and governments to improve the integrity and provenance of pharmaceutical products and medical supplies, as well as food, goods and industrial and consumer products.

The press release elaborates further, adding that the toolkit announced had been over a year in the making, with multiple stakeholders involved around the world, *including governments, companies, start-ups, academic institutions, civil society, international organizations, and technology and supply chain experts.* Special

attention in the press release was given to fundamental and resilient supply of products and services essential for the safe, secure, and robust functioning of everyday life globally. (Reportedly, the carbon footprint of blockchain is of sizeable proportions (Liu et al. 2019; Stoll et al. 2019).) It remains to be seen how supply chains and networks, tools, and methods may change in specific implementation and generic form in a post-pandemic world.

Summary

Supply chain management is being tested and redefined by contemporary events within the economy and industries across the world, the most prominent and visible of which is the global pandemic that endures at the time of writing. The notion of supply chain management is intrinsically connected to several key features of modern-day business activity: ICT/information and communication technologies; automation; electronic data interchange; and viable solutions for economic, social, and environmental aspects of sustainable business and economic activity. By their very nature, supply chains are integrative, yet their fragility has been proven by the impact of the global viral pandemic. It appears that, the more refined and advanced and reliant on technology, outsourcing, and globalized labor/services/goods output a supply chain is, the more susceptible it is to the “acts of God” events such as the global outbreak that seems to be reshaping our world. Conversely, it seems that the more conservative supply chains with greater sunk costs and fewer international interdependencies have performed better at the wake of the outbreak. This may be changing, as business and technology solutions are being sought to make them more robust. One technology that seems to be rising to prominence in the post-pandemic world is blockchain, itself essentially connected to the notion of supply chains: an information tech with WEF backing.

Definition/Description

Sustainable connotes anything that can be sustained or maintained for a long time, even forever. In the contemporary context, it generally refers to the use of natural resources. Sustainability acts in a way that the present generation uses natural resources to satisfy its needs in a way so as to leave enough for the future generations to satisfy their needs.

The key idea of sustainable development is expressed as: “to meet the current needs without destroying the ability of future generations to meet theirs.” This idea was proposed in 1987 by the United Nations’ World Commission on Environment and Development (WCED). The WCED is popularly called the Brundtland Commission. It published this definition in the book *Our Common Future*. Sustainable development is growth of the economy in such a manner that it provides enough for sustaining the present generation while leaving the natural system in a state that it continues to provide for the economic sustenance of the future generations.

Introduction

Sustainability is a widely used term. The dictionary meaning of the term “sustainability”

connotes any activity that is capable of being sustained, that is, it can be continued indefinitely or at least for a very long time. Thus, any term prefixed with “sustainability” or “sustainable” can be assumed to be a phenomenon or activity that can be continued indefinitely. Sustainable farming could mean farming methods and practices that could go on being used indefinitely. Sustainable business may mean those businesses that could be carried on profitably for an indefinite time. Sustainable development could thus be economic development that is feasible to be undertaken in the long-term without any noticeable negative impact on the environment.

The term “sustainability” and “sustainable development” have been defined in various ways by a number of scholars and practitioners over time. The concept of “sustainable development” was articulated by the Brundtland Report published in 1987. The Report was prepared by the World Commission on Environment and Development (WCED) of the United Nations, headed by Gro Harlem Brundtland, a Norwegian politician. It is also popularly known as the Brundtland Commission after her surname. It is to be noted that the WCED defines sustainable development and not sustainability.

The definition of sustainable development by the Brundtland Commission is stated as: “...development that meets the needs of the present without compromising the ability of future generations to meet their own needs.”

Besides the above definition, the WCED report elsewhere explains sustainable development in these words: “A process of change in which the exploitation of resources, the direction of investments, the orientation of technological development; and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspirations” (WCED 1987, p. 43 of 300).

Difficulties in Defining “Sustainability” and “Sustainable Development”

There have been several attempts to define the terms “sustainability” and “sustainable

development” over the years. These efforts were particularly pronounced after the WCED came out with its definition in 1987.

O’Riorden (1985) commented on the difficulty of defining sustainability, describing the process of trying to define it as: “Exploration into a tangled conceptual jungle where watchful eyes lurk at every bend.” Such a statement reflects the challenge in attempting to define or even explain the meaning of the term “sustainability” and “sustainable development.” The reasons why the field of sustainability seems a “tangled, conceptual jungle” are several. First, the issue of sustainability has gained so much importance in recent years that there are multiple efforts at defining it resulting in too many definitions. Secondly, there is lack of consensus on what exactly the term “sustainability” means. Such lack of consensus is understandable as there are too many experts working on the idea in so many different fields of human activity. Everyone looks at sustainability from the prism of their own narrow disciplines and specialties leading to multiple as well as differing perspectives. Lastly, practitioners exhibit little patience with finely devised definitions and prefer action over theorization. In different fields, implementation plans simply avoid defining “sustainability” as there are too many diverse definitions to choose from. In practice, it is generally found more feasible to adopt a working or operational definition that serves the limited purpose of implementation.

Criticism of the WCED Definition of Sustainable Development

Reiterating the definition of sustainable development by the Brundtland Commission “...development that meets the needs of the present without compromising the ability of future generations to meet their own needs” is necessary to look at point of criticisms of this definition.

The Brundtland definition of sustainable development places emphasis on long-term perspective and the ethical connotations of sustainability. Critics point out that it does not, however, identify the necessity for sustainable

environment, a society that provides a fair deal to its members and an economy that is working well. Several critics have pointed out that these features are essential to understanding sustainable development and should be a part of any good definition of sustainable development.

Costanza and Patten (1995) opine that critics have argued that sustainability cannot be adequately defined because of a few reasons. Among these is the futility of posing the challenge of sustainability as definitional rather than one of discussing of what will be sustainable or arriving at a consensus on what do we want to be sustainable. There is also the problem of sustainability not being applied over time and space.

Some critics allege that the major drawback of the Brundtland definition is that while it is certainly inspirational in nature, it is definitely not practical as it cannot be used in implementation. It is neither precise nor measurable. No one seems to agree on what it actually means. Over the years, it has been interpreted and misinterpreted to mean whatever the protagonists may want it to mean.

It is often mentioned in literature on sustainability that the term “sustainable development” is an oxymoron as sustainability and development are mutually incompatible. The logic is that for society to develop it must necessarily use more resources. If the society lives within sustainable means, production and consumption should actually be decreased or at least held constant.

Critics put forth the argument that if sustainability is taken in the sense of something being continued indefinitely then it does not match the requirement of the sustenance of physical environment. The ecology of earth is the outcome of billions of years of evolution. There are natural disasters that harm the ecology but it has the capability to rebuild and rejuvenate though it takes a lot of time to do so. But man-made harm exceeds the capacity of the earth to heal itself. Thus, sustainable development is a chimera as one cannot pursue two mutually opposing goals.

Perhaps the most strident criticism of the Brundtland definition and, in general, the idea of sustainability and sustainable development is the allegation of critics that it is a cover for businesses to carry on their harmful operations without

bothering about the physical environment. The concern for environment is only a smokescreen to hide the true intentions of businesses that is only profitability at any cost. The term “greenwash” has been devised to represent a situation where businesses present misleading information deliberately to present a favorable public image in order to hide their true intentions or to put a cover over their environmentally harmful activities.

Summary

The popular term “sustainability” has been defined in several ways over a long period of time. The effort to define it gained momentum after WCED mentioned both sustainability and sustainable development in its report *Our Common Future* published in 1987. It was defined in terms of the prudent use of natural resources. Sustainability could be achieved if the present generation used natural resources wisely leaving enough for the future generations. Sustainable development was visualized as an economy that could develop by using natural resources without causing excessive harm by indiscriminate exploitation.

There have been innumerable attempts at defining sustainability and sustainable development before 1987 and these have continued later. The WCED definition did not help to close the matter. Possibly this is because of the nature of the term sustainability. It is taken to mean so many different things depending on diverse perspectives. It is a complex issue. In practice, sustainability is defined in operational terms, satisfying the requirements of the situation that is being dealt with.

There is much criticism of the WCED definition ranging from a simple accusation of it being simple, simplistic, or being inspirational rather than of being of some real use. Sustainability and sustainable development are both criticized on several counts. The primary criticism is that the term sustainable development uses two words that are mutually contradictory. Anything that aims at economic development cannot be sustainable. There are other points of criticism among them

the more scathing is that businesses use sustainability as a cover for their environmentally harmful activities.

The controversies over the definitions and the meaning of the terms sustainability and sustainable development are not going to die down any time soon.

Definition

Since the premiere of the Sustainability Accounting Guidelines in August 2002 at the World Summit on Sustainable Development in Johannesburg, sustainability accounting that was initiated by Rob Gray has attracted sustained attention since the early 1990s in various academic accounting literature and has been recognized as the most evolved form of environmental accounting (Lamberton 2005). Gray et al. (2014) proposed three distinct techniques of sustainability accounting based on this concept: (1) sustainable cost, which is the (hypothetical) expense of recovering the Earth to its pre-organizational state; (2) natural capital inventory accounting that entails the tracking of natural wealth through time, with fluctuations in holding levels used as an indicator of the (decreasing) value of the natural environment; and (3) analysis of the input-output relationship, which aims to estimate the price of bringing the world to its post state. The study takes into account the physical material flow and energy sources or inputs, as well as the production of goods and waste in physical units.

Generally, sustainability accounting can be defined as a management scheme used by a company by including nonfinancial information related to its ecological, social, and financial impacts on the planet and in surrounding communities, as stated by the Sustainability Accounting Standards Board (SASB 2017), because it represents a company’s stewardship of its environmental and social implications associated with the producing goods and services and also the governance of the environmental and social capitals necessary to generate lengthy values, including that of the effects of challenges and opportunities on innovation, business models, and governance practices, and vice versa.

Introduction

Sustainability accounting has progressed over the last four decades, allowing for a better knowledge of how accounting tools and processes help business sustainability management. According to the empirical contributions of critical academics,

firms have failed to meet high sustainability goals and have used environmental disclosure to conceal their bad performance (Ehrenfeld 2005). Thus, in the opinion of these critical academics, sustainability accounting serves an extremely restricted function in aiding corporate sustainability and may be phased out in the future. The pragmatic approach, on the other hand, emphasizes the purpose from a management standpoint, which is to give a collection of tools that assist corporate managers when considering sustainability.

Sustainability accounting is a variation on standard financial or management accounting since, unlike traditional financial accounting, it promotes knowledge of company sustainability and environmental implications. Its primary function is to innovate or further alter standard accounting concepts in order to assist management in fostering a company's long-term success. Nonetheless, the debate over the adoption of corporate sustainability principles, as well as the best way to apply these standards, yields contradictory results. Therefore, corporate management has varying interpretations of the function of accounting for sustainability, which is reflected in distinct implementation methodologies.

Sustainability accounting seeks to account for firms' relationships with society and the natural environment (Peršić et al. 2017). It is a framework for reflecting on and illustrating the economic, social, and environmental repercussions. Companies have used sustainability accounting as a management tool to demonstrate the link between ecological and socio-impact in order to fulfill financial impacts goals. It made a name for itself in the domains of social and environmental accounting, corporate responsibility, and nonfinancial accounting. Furthermore, unlike conventional accounting, which is concentrated on assembling, recording, and presenting financial occurrences that have an influence on the company's financial condition as well as its long-term viability and earnings, sustainability accounting, as an integrative approach, is aimed at providing reliable and realistic information to various stakeholders on the human and ecological elements of business practices (owners, managers, creditors, auditors, etc.) (Fülöp and Hernádi 2013).

Key Issues

In *Accounting for Sustainability: Asia Pacific Perspectives*, Lee and Schaltegger (2018) encouraged all of the book's contributors to provide their perspectives on sustainable accounting or accounting for sustainability. Some writers describe their strategy to sustainability accounting using the Brundtland Report's wide concept of sustainable development. While some use traditional accounting, others use a more practical approach to accounting for sustainability. Disagreements in perspectives may arise as a result of misunderstandings about what sustainable development stands for and how it pertains to sustainability accounting, uncovering some key troubles in the area of rich diversity, the dispersion of different goals subsumed under "sustainability," and the challenge of incorporating the perspective.

According to Schaltegger et al. (2006), while the term sustainability accounting refers to the most current information management and accounting methodologies that focus on creating and provide elevated information to help a company shift to sustainability, the term sustainability reporting refers to new formalized and structured form of communication that presents information about corporate sustainability. The objective of sustainability reporting is "to inform development of an integrated business strategy for corporate management and assess sustainability risks and opportunities inherent to investment decisions" (SASB 2017).

There are different sorts of sustainability accounting: internal and external. The internal component represents sustainability issue management, and the external component involves official reporting of these concerns, also known as sustainability reporting (Stacchezzini et al. 2016). Sustainability accounting and reporting may be described as an organization's response to managing and reporting a company's concerns related to sustainability topics in order to legitimize corporate activities through a social compact.

Sustainability accounting is a key aspect of strategic accounting, and it is a significant tool for detecting, evaluating, and managing social

and environmental hazards through recognizing resource efficiency, utilization, and cost savings. It integrates environmental and social challenges with financial potential. As a result, sustainability accounting refers to that portion of accounting that takes into consideration the actions, techniques, and systems used to record, evaluate, and report on the financial and ecological and social implications of a given economic system (e.g., the company, production site, nation, etc.). Schaltegger et al. (2006) stated that sustainability accounting examines the relationships and interdependence of social, environmental, and economic challenges, which comprise the three pillars of sustainability. Its goal is to assess companies' environmental, social, and governance performance by examining how they manage several types of nonfinancial capital related with sustainability (environmental, human, and social) and corporate governance challenges, on which they rely for long-term value development.

Finally, the purpose or objective of sustainability accounting is to provide information and statements relevant to internal stakeholders for the development of an integrated business strategy and managing corporate sustainability and to also provide information that is relevant to external stakeholders for risk assessment and opportunities inherent in investment strategies. As a result, determining the framework of strategic accounting is critical when structuring corporate sustainability accounting. On a strategic level, the complete sustainable accounting framework is supported by numerous critical components: goals, guidelines, data collection methods, accounting records, measurement procedures, reporting to stakeholders, and qualitative information attributes (Lamberton 2005).

Sustainability accounting and reporting, which cater to the gathering, analysis, and transmission of corporate sustainability information, have emerged as critical management tools for achieving corporate sustainability (Schaltegger et al. 2006). Sustainability accounting and reporting must be able to facilitate information on the company's performance and development progress in respect to all corporate sustainability difficulties, including contextual factor and

additional challenges, in order to assist management.

Sustainability accounting and reporting, which must offer the company's management with unbiased actual information and data for making triple bottom-line choices, imposes cost on organizations who undertake the conduct or practice and realization. In the economic realm, the costs should be offset by rewards that outweigh the costs in order for the spending to be justified.

In terms of participation, sustainability accounting and reporting may include corporate social responsibility (CSR) accounting, which should not only cover the company's CSR achievements, performance, and contributions but also address the information requirements or needs and disclosure of the expenses and gains associated with relevant stakeholder. Corporate sustainability is not confined to the corporate organization itself but also draws attention to the corporation's social embeddedness and the influence it has on its social environment, as a result of the wide approach and its varied contextual components.

Ecological and socio-management, as well as sustainability accounting and reporting, are typically used in tandem with traditional management method and techniques. This may result in wasted knowledge of management and business solutions where, for example, attempts to develop creative goods and other process-based improvements aimed at sustainability are not identified early enough. As a result, one of the primary difficulties for sustainability accounting and reporting is the merger of environmental and social accounting and reporting methodologies into core company management processes and systems. Corporate sustainability management, particularly sustainability accounting and reporting, is therefore pushed to reform an organization's traditional business environment through methodological and information transformation.

Schaltegger and Burritt (2010) outline six specific reasons for adopting sustainable accounting, three of which are directly connected to gaining the permission to function, including greenwashing, industry pressure, and governmental and stakeholder intimidation. Greenwashing is

depicted as a technique to boost communication activities with less engagement in significant sustainability actions, whereas industry and stakeholder pressure is seen as a reaction to urgent shareholder concerns. The other three reasons for implementing sustainability accounting are corporate responsibility, sustainability as a business case, and self-regulation, all of which need proactive participation. Accountable information is required for corporate responsibility, which may be obtained through sustainable accounting. Furthermore, sustainability accounting may aid in the justification of a corporate strategic plan and may result in cost savings or incremental income, creating a major victory scenario in terms of environmental/social and financial sustainability. The last reason is that the corporation commits to meeting specific conditions in order to avoid further necessary restrictions, often known as self-regulation.

Natural capital and ecosystem services are becoming increasingly important in sustainable accounting. Natural capital, in its most basic form, refers to holdings of environmental assets from which flows of ecosystem services contribute to human benefits. Accounting flows from natural, regenerative, and biological mechanisms are sought for by sustainability accounting (Fenichel and Abbott 2014).

Accounting for corporate sustainability challenges a new perspective that improved management and reporting systems, new accounting structures, and new data and analytical tools to better analyze and manage scarce resources and natural capital's continuous productive capability. Planning for the future, a technique of process of well-functioning organizations and governments, is simply less viable without precise accounting and reporting systems, and sustainability reporting will become part of these systems.

To begin to investigate what an account of (un)sustainability would look like, one must turn to the variety of experiments present in the business and academic literature. There are three basic ways to building a sustainability story: those that focus on indicators, those that utilize a financial narrative (financial quantification), and those that

use other nonfinancial quantitative narratives (nonfinancial quantification).

Summary

Companies must now discover a solution to make social, environmental, and economical challenges work together, as well as the importance of sustainability accounting in the process. Sustainability accounting examines the relationships and interdependence of social, environmental, and economic challenges, which comprise the three pillars of sustainability (Schaltegger et al. 2006). In terms of terminology, sustainability accounting refers to accounting methods that generate and disseminate high-quality information to help a company achieve sustainability, whereas sustainability reporting is a new standardized methodology of communicating and presenting information regarding company sustainability.

There are two reasons why the integration of sustainable accounting and reporting is critical. First, uncommunicated accounting information has no effect and hence cannot contribute to the company's long-term success. Second, reporting is necessary to validate information regarding the current state of, and progress toward, business sustainability; otherwise, the information is seen as shallow.

For meaningful contributions to corporate sustainability, sustainability accounting and reporting should be included in a structured sustainability approach to performance management. As a result, sustainability performance management could be divided into strategy and sustainability reporting that is driven by conventional accounting standard (the "inside-out perspective"), which is characterized by reporting that is planned and achieved on the basis of corporate strategy, accounting, and management performance, and sustainability accounting that is driven by an appropriate reporting methodologies (the "outside-in perspective"), which is characterized by reporting that is driven by reporting and cohesion. External rules, grading, and assessment schemes set information needs and indicators for reporting-driven, sustainable accounting, which

in turn define accounting processes and information management systems.

Sustainability accounting and performance management cannot be effective unless the societal and corporate environments are considered. Sustainability reporting has no relevance unless it is based on credible information and performance. As a result, corporate management must address stakeholder perceptions and expectations if efforts and performance gains are to be recognized and company sustainability is to be improved. This suggests that both the “inside-out” and “outside-in” viewpoints have advantages and disadvantages, and combining them may be the most beneficial.

Understanding nonfinancial risks and opportunities and demonstrating how they are managed is what CSR requires for firms. Sustainability accounting is a management tool that supports managers and other stakeholders in giving a reflection of previous performance as well as a forecast of future performance in terms of social, environmental, and financial objectives. The purpose of sustainability reporting is to promote transparency and accountability while also allowing for more knowledgeable and reliable judgment in a context where monetary and nonproblems are becoming increasingly intertwined. Unlike in the past, where the emphasis was mostly on the historical performance of indicators, the attention these days is more clearly on understanding environmental challenges and their relationship to core business. As a result, in complex business contexts, sustainability accounting becomes crucial as a key tool for organizations to grasp the complexity of business environments and build a cohesive plan to address significant challenges and deliver long-term value.

Sustainability Accounting Standards Board (SASB)

Nicolás García-Torea

Department of Economics and Business
Administration, Universidad de Burgos, Burgos,
Spain

Definition

The Sustainability Accounting Standards Board (hereafter SASB) is a nonprofit organization

founded in 2011 that develops industry-specific sustainability accounting standards for the production of information on material nonfinancial topics for US investors. Currently, SASB has produced sustainability accounting standards covering material issues for 77 industries that operates in ten different sectors. SABS aims that its standards will be integrated into listed companies' filings to the Securities and Exchange Commission. This chapter provides a brief description of SASB as an organization and its governance structure. Afterward, it summarizes the key characteristics of the process that SASB follows to develop the standards. This process is based in industry expert feedback and public consultation. The chapter concludes with some guidance offered by SASB on how firms should apply their guidelines when producing disclosures on material social, environmental, and governance topics.

Introduction

The Sustainability Accounting Standards Board (hereafter SASB) is a nonprofit organization that produces sustainability accounting standards that guide firms to report on environmental, social, and governance material topics for investors within a specific industry. SASB was founded in 2011 with the purpose of offering the providers of financial capitals, mainly investors, information that allows them to evaluate the nonfinancial impacts of the corporations in which they invest or plan to invest. As acknowledged in its webpage, SASB expects to help the decision-making process of investors by promoting a "shared understanding of companies' sustainability performance" and increase long-term value creation by promoting sustainability.

In contrast to previous global international initiatives for the elaboration of sustainability disclosures, such as the Global Reporting Initiative or the International Integrated Reporting Council, SASB focuses on US listed companies (Flasher et al. 2018). Specifically, it seeks that its sustainability accounting standards will be integrated into the 10-K and 20-F mandatory filings of the

Securities and Exchange Commission (hereafter, SEC). The organization has the accreditation of the American National Standards Institute that guarantees that its sustainability accounting standards are developed through an open, balanced, consensual, and due process (Khan et al. 2016).

Another significant difference with respect to Global Reporting Initiatives is the targeted audience of the information produced with the standards. While the Global Reporting Initiative Standards aims to elaborate useful information to firms' key stakeholders, SASB, similarly to the International Integrated Reporting Council, focuses on producing disclosures that are relevant for the participants of capital markets. This is consequent to the growing relevance of certain social and environmental topics for investors, as shown in the increasing number of CSR resolutions submitted by activist shareholders (Proffitt and Spicer 2006). In this regard, SASB covers those particular nonfinancial issues that could end up in having an impact in the financial performance of firms.

SASB Organizational Structure

SASB is dependent on the Sustainability Accounting Standards Board Foundation (hereafter SASB Foundation). Similarly to Financial Accounting Standards Board and the International Accounting Standards Board, the SASB Foundation has a dual governance structure: the SASB Foundation's Board of Directors and the Standards Board. On the one hand, the SASB Foundation's Board is the governance board. It is in charge of deciding strategic and operational issues. It is also responsible for monitoring the Standards Board and nominating its members. On the other hand, the Standards Board is the technical board, and it is in charge of the standard-setting process itself.

As stated in its webpage, the SASB Foundation gets no governmental funding. Its financial resources come from two different sources: (i) contributions from private individual, firms,

and philanthropic entities and (ii) commercial activities (e.g., publications, training, etc.).

Sustainability Accounting Standards and the Standard-Setting Process

The sustainability accounting standards cover material topics for investors that are industry-specific. As of November 2018, SASB has produced standards with suggested metrics for 77 industries across 11 sectors. The standards are considered to be easy to be implemented by companies.

The standards are included in the SASB Materiality Map. The SASB Materiality Map is an interactive tool that identifies material topics for each specific sector and industry. Once that companies determine their material topics using the Map, they can download the corresponding standard to report on them.

Each standard provides explanations on three areas. Firstly, it offers accounting metrics for the material industry-specific issues. Secondly, it includes a technical protocol that guides firms for the compilation of data. Finally, it also provides metrics for normalization (SASB 2018).

SASB's standard-setting involves a five-phase process. In the first and second phases, SASB gathers feedback from research and expert consultation, respectively (Lee et al. 2018). Afterwards, in the third phase, the outcome of the two initial phases is subject to a technical analysis by specific industry-working groups. During these three phases, SASB performs a materiality test to identify which are the material topics for the industry. Khan et al. (2016) describe the way in which SASB conducts this test that consists of three elements: the interest test, the financial impact test, and the forward-looking test. The interest test evaluates the relevance of an issue through (i) a keyword search in Bloomberg as well as in SEC filings and documents and (ii) the assessment of the industry-working group participants. The financial impact test evaluates the influence of a topic on the financial situation and performance of firms. This test relies on investor

and market data and news. Finally, the forward-looking test evaluates the likelihood of the future financial impact of a topic that fails to meet the financial test but that could be material for financial capital providers. The outcome of phase 3 is an exposure draft (fourth phase, which is open to public consultation for 90 days during the fifth phase). The final standard is published considering the feedback obtained during this consultation period and after the review of the Standards Board. SASB allows the possibility of updating the standards to make changes and adjustments (Khan et al. 2016).

The composition and functioning of the industry-working groups is described in SASB industry-working groups due process report (SASB 2015). These groups include members from three different types of stakeholder groups with experience in the specific industry: financial statement preparers, information users, and public constituencies (Flasher et al. 2018). The feedback from the industry-working group is collected by means of an online survey and outreach consultation (Khan et al. 2016).

Application of the Sustainability Accounting Standards

SASB published a document that offers guidance on how companies should apply the standards (see SASB 2018). The standards distinguish three types of elements. Elements introduced by the term “shall” are required should the company seek their disclosures to be considered in accordance with the SAB standards. Elements introduced by the term “should” offer recommended guidance. Finally, elements introduced by the term “may” offer optional guidance.

Regarding the reporting boundaries to be considered when compiling data, SASB states that the firm should consider the same entities that are included when producing consolidated financial statements.

In relation to the reporting format, SASB provides the following suggestion when applying the standards. First, the financial data included in

nonfinancial disclosures should be aligned with the data provided in the financial statements. Second, metrics should be normalized and be expressed in the International System of Unit so that an adequate comparison and benchmarking is enabled. Third, the firm should also describe the uncertainty related to the reporting of certain aspects, as well as the estimates used for measuring certain elements. Fourth, the information provided should be referenced to the firm's fiscal year.

Finally, SASB allows firms to omit disclosure topics or specific metrics, as well as to make change to metrics. However, both omissions and changes should be disclosed as well as their justification.

Sustainability and NGOs

Huriye Toker
University of Yasar, İzmir, Turkey

Synonyms

Pressure groups; Social movement actors and local-community actors; Sustainability and community-based organizations; Sustainability of anti-market environmentalists; Sustainability of civil-society organizations; Sustainability of non-profit organizations; Sustainability of the third sector

Definition

Non-governmental organization (NGO) is an umbrella term to define many organizations ranging from transnational federations to grassroots or community-based organizations at local, national, or even global levels. It includes any independent voluntary group of people acting together on a continuous basis for some social, cultural, legal, or environmental common purposes, other than making money or illegal activities. Sustainability in the framework of NGOs has two perspectives. Firstly, sustainability of NGO means being able to survive so that the NGO can continue to serve its constituency and fulfil its commitments to the

community within which it operates. In order to sustain itself, an NGO must ensure a flow of social, financial, and human resources. From the second approach of meaning, sustainability of an NGO underlines the NGOs role in improving sustainability practices of business organizations.

Introduction

Non-governmental organizations (NGOs) have existed in various forms for many centuries, but the term “NGO” was first used in the United Nations’ (UN) Charter in 1945 to differentiate it from international private organizations. Although there is no generally accepted definition for NGOs, they can be defined as social, cultural, legal, and environmental advocacy groups that have noncommercial goals (Toker 2013) and that are independent from government, party political, and economic actors and not engaged in criminal or violent activities. In another definition, an NGO is classified as a commercial entity that earns the majority of its revenue through projects or donations, relying primarily on outside sources of funding (Hansmann 1980). NGOs are mostly established for “charitable purposes to assist with social and community development, providing services free of charge to beneficiaries and gains capital through donations and grants” (Willets 2002). Their functions include public health and safety; education; charity; the provision of food, clothing, and shelter; labor; sports; politics; religion; advocacy; philanthropy; business support; and civil rights.

The second term sustainability is no longer a new buzzword in business; rather, it is something that many companies in various industries have begun to take very seriously. The term, which was first used in the UN’s Brundtland Report in 1987, refers to action that “meets the needs of present without compromising the ability of future generations to meet their own needs” (Brundtland et al. 1987, p. 16). That is, society must use more of a resource than can be regenerated. Sustainability is a broad concept that encompasses regulations, systems, ratings, trends, and developments in

business ethics, corporate social responsibility, reputation management, and accountability.

The term sustainability also includes “the acceptance of any costs involved in the present as an investment for the future” (Crowther 2012). The word is mostly used within the framework of sustainable development and concerned with the effects that actions taken in the present have on the options available in the future. The issue of sustainability has risen to prominence recently, not just in business and academia, but in popular consciousness as well. It has been popularized in the general community by talking about carbon footprints. Businesses, too, are making statements about their aims for carbon neutrality.

Sustainability in relation to an NGO has two dimensions. Firstly, it relates to the social and financial survival of the NGO which can fulfil its commitments to the society. Secondly, sustainability of NGOs also highlights the ever increased NGOs role in improving sustainability practices of business organizations.

The Relationship of Sustainability with NGOs

Marshall McLuhan’s declaration that we live in a global village (1967) in which technology connects everyone has become a motto to explain our relationship with the internet and social media. Today, governments and nation states are becoming less important, while multinational companies operating in a global environment have become more powerful and able to draw the boundaries of our village. However, technology has also opened up business to public scrutiny and empowered individuals as customers and concerned citizens. This is thus an era of power redistribution, which has resulted in increasing concern with ethics, human rights, and environmental issues. A concern for sustainability highlights the triple bottom line – Brundtland’s three pillars of economic, environmental, and social – and their equal importance.

The relation of sustainability and NGOs has two aspects. Firstly and generally sustainability of

an NGO means its survival as an organization in the society. Secondly, the term sustainability of NGOs refers to the increasing role and relation between the NGO and actions of companies in the field of sustainability. Since sustainability is a complex subject that is not only related with physical environment, NGOs these days are evaluated with NGO sustainability index which monitor an NGO across seven interrelated dimensions ranging from legal, environmental, financial capacity to infrastructure, advocacy, and even public image.

Since the 1990s, due to the collaboration of business and NGOs in sustainability-related issues, a growing number of leading companies are taking the challenge of sustainability seriously, with reducing their environmental footprint and bolstering their reputations but also improving operations and financial performance. In ecosystem challenges, business mostly partners up – with governments, investors, local communities, NGOs, and other companies as joint ventures – often with multiple parties. The Marine Stewardship Council (MSC) is a good example for the NGO and business collaboration in the sustainability topic. It is a partnership that sets standards for the fishing industry, struggled in its first few years with high staff turnover and unstable funding. In the past decade, however, it has become a force. Its certification standards cover 10% of the global seafood harvest, and almost a quarter of global shoppers recognize the MSC label. This covers more than 20,000 products sold in over 100 countries (Albani and Henderson 2014).

“Grow Africa” is another good collaboration example between the World Economic Forum and the African Union to enhance food security in Africa. It is a public-private partnership platform established in 2011 which focused on increasing private investment in African agriculture. And in 2012, US President Barack Obama threw the G8’s weight behind this partnership approach for African agriculture by announcing the New Alliance for Food Security and Nutrition. By the end of 2012, the G8’s New Alliance and Grow Africa worked closely to secure more than \$3 billion in private-sector investment commitments from

nearly 50 local and global companies (Albani and Henderson 2014).

The third example is the collaboration success between Unilever and the World Wildlife Fund (WWF) in 1997 committed to the clear goal of encouraging sustainable fishing practices (Albani and Henderson 2014). The partners, using the successful Forest Stewardship Council (FSC) as an example, started by consulting with stakeholders such as commercial fishermen, governments, and environmental organizations. Only then did they design the standards for what constituted sustainable fishing practices and seafood traceability; these are reviewed on a regular basis. In 1999, the MSC began operating as an independent nonprofit, free of Unilever’s and WWF’s control, and it is changing the fishing industry beyond the 10% of fisheries that have signed up (Albani and Henderson 2014). Over time, as trust and confidence build and as the group moves from design to institutionalization, a successful collaboration can and should phase out the facilitator. Ideally, individuals who started out as representatives of companies with competing interests become a cohesive group working toward a common goal of sustainability.

Thus, sustainability mostly refers human impacts on nature, environment, and the resource base shortly called people, profit, and planet (Elkington 1998). There are financial, environmental, and social aspects to the issue. Research starting as early as 1999 has looked at sustainability from five different angles: **consumer** sustainability, **firm/organization** sustainability, **societal** sustainability, **laws and regulations** defining sustainability, and **scholarly** defined sustainability (McDonagh and Prothero 2014). Consumer sustainability deals with individual sustainability issues, consumer behavior and practices, values, and preferences in sustainable consumption. Organizational sustainability researchers investigate the sustainability practices of firms and markets. Marketing communication, promotional activities, product development, and design also fall within this field, which conceptualizes and reframes sustainability in terms of institutional, social, and system perspectives, while theorizing the concept of sustainability. The investigation of

sustainability in relation to laws and regulations explores legislation about sustainability within a society, such as environmental laws, regulations, and public policies. The last area of sustainability research deals with a spectrum of sustainability-related issues to provide a broad literature review (Yüksel and Çalıyurt 2017, p. 288).

Regarding NGOs, sustainability primarily means “being able to survive so that the organization can continue to serve its constituency and fulfil its commitments to its supporters and the community in which it operates” (Weerawardena et al. 2010). NGOs emerge to satisfy a need that neither business nor public sectors can satisfy (Etzioni 1972). Theoretically, an NGO is neither financially sustainable using a for-profit business model nor receiving sufficient public support to move governments to action (Hansmann 1980; McDonald 2007). Yet despite these fundamental challenges, the nonprofit sector has become larger than ever and continues to grow in an increasingly competitive environment. The bulk of research in the field is focused on balancing money and mission as primary issue in managing NGOs. An NGO must “ensure a flow of resources in order to sustain itself through earned income, governmental support and private donations” (Bryson et al. 2001; Valentinov 2008). Thus, financial sustainability is crucial for the long-term survival and effectiveness of all types of international NGOs. The challenge to achieve such levels of financial sustainability of an NGO depends on its ability to diversify income and access new funds.

Sustainability is also a controversial topic because it means different things to different people. Firstly, there is a general acceptance that sustainability is synonymous with sustainable development, which attempts to bridge the divide between economic growth and environment protection. However, sustainability also refers to “the ability to continue in an unchanged manner or development in a sustainable manner” (Hart and Milstein 2003). Secondly, a sustainable organization can survive merely by recognizing environmental and social issues and incorporating them into its strategic planning. These perceptions consider sustainability as a two-dimensional environmental and the social approach. There are four

aspects of sustainability that need to be recognized: **societal influence**, which defines the impact of society on organization; **environmental impact**, which defines the effect of the organization’s actions of the upon its geophysical environment; **organizational culture**, the relationship between the organization and its internal stakeholders, particularly employees; and **finance**, providing an adequate return for the level of risk undertaken (Crowther and Seifi 2017, p. 20).

Although sustainable development is often discussed as an environmental issue concerned with resource depletion or energy consumption, it is actually a much broader concept concerned with economic, environmental, and social policy. It should not only be considered for its contribution to financial performance measures but is a value-added activity from both organizational and consumer perspectives. Ethics and business ethics play an important role in understanding the importance of sustainability. Future sustainability research should take this holistic approach into consideration as these three pillars have not yet been treated as equal, with economic sustainability particularly neglected. While there are many answers to the question of sustainability, it is important to ask the right questions to find the most appropriate answer. Sustainability-related debates are relevant to all of stakeholders, whether as consumers, employees, investors, citizens, or managers of future generations.

Sustainability was initially considered a “fad,” but economic crises show that being sustainable means surviving. Sustainability protects the organization against economic crises, environmental disasters, pollution, global warming, and energy shortages, improves staff loyalty, and raises share value. To create a sustainable environment, we must train people from different disciplines and urge them to learn more about sustainability issues in their own areas. Accordingly, many companies have recently created the position of “sustainability director,” which is a clear indication of the concept’s emergence in the business world.

Today, many firms worldwide monitor their business operations in terms of social, environmental, and sustainability practices because the CSR and sustainability have become a public

interest issue in the last 20 years (Sen and Bhattacharya 2001). A growing consumer movement, which first gained power after the 1960s, has developed organized and collaborative campaigns worldwide, which have influenced how firms perceive and engage with CSR. Through their CSR activities, NGOs participate in the sustainability actions of business. For example, Greenpeace's campaigns targeting unsustainable environmental practices have attracted attention to sustainability. Moreover, these collective actions have been shared on blogs and social media to influence companies' response strategies. Thus, sustainability involves a holistic process of continuity, competence, efficiency, resourcefulness, and responsibility, which provides benefits for all stakeholders. By following sustainable practices, an organization may reduce its energy, water, waste, and materials costs. Sustainability programs should be embedded into all levels of organizations, aligned with all other strategy and plans, and audited systematically.

The NGO sustainability these days has become more institutionalized. There is an NGO sustainability index which assigns scores to NGOs according to seven interrelated dimensions. These criteria are related with legal, organizational, and financial capacity of an organization. However organizational dimensions are important, NGO sustainability index also monitors advocacy, service, infrastructure, and public image performance of an NGO to assign them as a viable organization. Sustainability is a complex, interlinked subject that is not restricted to the physical environment. NGOs confronted with increased competition must reflect on the strategies to follow to achieve greater organizational sustainability. NGOs can adopt entrepreneurial strategies to increase sustainability, as can for-profits. Successful nonprofits are also constantly vigilant to reduce costs over the long term, as can for-profits. Both can seek mutually beneficial alliances to achieve their broader cost-related goals.

Summary

Non-governmental organizations (NGOs) or "civil society organizations" are any nonprofit,

voluntary citizens' groups organized on a local, national, or international level. NGOs perform a variety of services and humanitarian functions, bring citizen concerns to government attention, advocate and monitor policies, and encourage political participation through provision of information. As governments have lost power compared to corporations, NGOs and civil society groups have stepped in as a monitoring and enforcing actors of social and environmental standards. This enormous power shift also gives an opportunity to NGOs to become important actors, in both the social and economic sphere.

The term sustainability has different meanings and concerns for NGOs. From one aspect, it is related with financial viability or long-term economic growth; from another aspect, it is about environmental sustainability and addressing issues of climate change, population growth, and resource imbalances. Sustainable NGOs are those which are able to respond strategically and effectively to such external changes. They revise their mission and objectives accordingly, access new sources of income, and adapt their systems and processes to meet the new challenges. New methodologies are being developed to identify and assess the organizational characteristics of effective and sustainable NGOs. Commonly, these are based on an assessment of core attributes such as leadership capabilities and management competencies, the capacity to deliver specific services (health, education, etc.), or the ability to pay salaries and cover running costs. But increasingly they also include analysis of an NGO's ability to anticipate and handle change, in particular adapting to changes in the external environment and the consequences of such changes on their income as well as aging or outdated systems and processes. The trend seems to be one of developing greater independence and resilience through diversifying income sources and a willingness to explore more entrepreneurial routes to financial sustainability.

Not very long ago, the dividing line between business, NGO, and society appeared clearly drawn. Sustainability, as a core concept of strategic management, lies on this border. It is a new term to highlight human impacts on nature, environment, and resource base. Through a sustainability approach, the business world has tried to

understand, learn, and implement this concept in their management function. Faced with increasing social and economic problems, business has adopted more sustainable and socially responsible ways of doing business to adopt a corporate responsibility, which defines a firm's involvement in sustainability and social responsibility actions (Türker and Toker 2017, p. 161).

Today, there is a growing concern on economic development and sustainability. The term sustainability refers to financial, environmental, and social aspect of the issue. Regarding NGOs, sustainability primarily means being able to survive so that the organization can continue to serve the society. In a narrow sense, an NGO must ensure a flow of resources to survive.

The NGO sustainability index analyzes and assigns scores across seven interrelated dimensions: legal environment, organizational capacity, financial viability, advocacy, service provision, infrastructure, and public image. Sustainability is a complex, interlinked subject that is not restricted to the physical environment. NGOs confronted with increased competition must reflect on the strategies to follow to achieve greater organizational sustainability. NGOs can adopt entrepreneurial strategies to increase sustainability, as can for-profits. Successful nonprofits are also constantly vigilant to reduce costs over the long term, as can for-profits. Both can seek mutually beneficial alliances to achieve their broader cost-related goals.

Overcoming Trade-Offs

Definitions

In traditional business, there has long been a trade-off thinking between sustainability and profit. However, this paradigm is currently in flux. Issues such as the extinction of species or climate change are increasingly also seen as economic challenges. So, companies increasingly see themselves as part of society and see this role as an opportunity to impact positively

At the same time, rethinking and seeing an entrepreneurial opportunity in this change represent a significant challenge. However, this is the basis of sustainable business models - overcoming the dichotomy of profit and sustainability.

An important aspect is the combination of social and or ecological as well as economic effects. Sustainable companies that are not economically successful will not be able to stay in the market. Similarly, it is becoming increasingly apparent that companies without a social/ecological impact are less and less successful economically. This social/ecological effect can arise because negative is avoided and/or positive values are created

The positive economic effects of such sustainable companies are now also recorded by

international studies. Thus, it was shown that increased sustainability has a positive effect on the economic future, and competitive advantages can be secured. These advantages can be seen above all in employee satisfaction, the reduction of corporate risks, increases in sales, increased customer loyalty, and the employer brand's strengthening

Current Business Models Are Coming under Pressure

To the question “profit or sustainability?”, the same answer is increasingly coming from business practice as well as academia: “Both!” Thus, a strong dynamic can currently be observed in large- and medium-sized companies. For years, the economic principle of pure profit maximization was considered sacrosanct, but this seems to be coming to an end. In the same way, society’s view of business is changing. Trust in the ethically correct actions of economic and political actors is increasingly declining. However, it is not only institutions that are being criticized; entire economic systems and countries are also losing trust in ethical correctness. So, it is not surprising that society sees change as inevitable [see (Edelman., 2019) (Edelman., 2020) (Edelman., 2021)]. More and more companies recognize that the planet is changing rapidly and that issues such as climate change or species extinction directly threaten life on planet earth. Accepting these challenges as a company and seeing them as an opportunity represents a new paradigm - entrepreneurial success through sustainability.

Sustainability is increasingly equated with future viability. Companies that refuse to embrace sustainable transformation will not be successful in the long term. In addition to the social issues, it is above all the ecological challenges that play a significant role. In contrast to traditional forms of business risk, social and ecological risks manifest themselves over a more extended period and lie outside the company’s active control radius. Thus, companies will be affected in different dimensions (e.g., by climate change). Therefore, risk management requires making investment decisions for longer-term capacity building and developing adaptation strategies (CDP, 2016).

Sustainability and Profitability,
Fig. 1 Current business models under pressure

Current business models are coming under pressure

For this reason, companies are increasingly under pressure to integrate the assessment of the critical environmental and social opportunities and risks of their investments into future earnings potential (Oekom, 2018). In addition to these factors, however, the business itself is also pushing for more sustainability. CEOs of global corporations and asset managers state that sustainability is essential to the success of companies and that sustainability contributes to profits [see (Winston, 2019), (BlackRock., 2021)].

Because it is clear that only those companies that also generate a benefit for their environment are successful in the long term. Furthermore, only these companies are attractive for future cooperation, such as employees, customers, investors, or other actors in the economy (Whelan & Fink, 2016) (Fig. 1).

Inclusive Growth through Sustainable Entrepreneurship

Successful companies of the twenty-first century are characterized by the fact that they have overcome the trade-off thinking between sustainability

and profit. Furthermore, these entrepreneurs think of the present from the future by integrating sustainable management into the company's strategy. In this way, they try to fulfil the desired positive future impact on society with a current business model, consisting of a combination of social, ecological, and economic components.

Currently, it is mainly recently founded companies which try to combine these two dimensions, "public welfare-oriented commitment" with "classic entrepreneurship" and thus create social entrepreneurship. It usually happens due to the desire to combine the meaningfulness of work and receive money for their own life design. Besides, the limits of growth as well as the limits of altruism form a limit for an economy based on pure profit maximization and pure philanthropy.

An important factor is the reorientation of management systems. Sustainable management must be integrated into the corporate DNA. This integration is the fundamental difference to the "old" CSR concept, in which sustainability stands exclusively next to the actual business activities without being included in the central business activities.

Sustainability and Profitability,
Fig. 2 New growth opportunities

Several industries have already experienced that overcoming the old trade-off between sustainability and profit is financially profitable and sustainable. For example, business models based on sustainable innovations showed new growth opportunities for entrepreneurs. By integrating good public components, incumbent corporations and companies are being driven from their position as market leaders. Many examples can be found, starting with the automotive industry in terms of alternative driving technologies, community-based knowledge portals, sharing economy in the accommodation industry, and sustainable online search engines (Fig. 2).

What Does this Mean for our Economy?

Instead of the profit maximization that had been pursued for decades, comprehensive value creation for all stakeholders and a positive impact on society are becoming the primary corporate goals. In doing so, leading managers fundamentally challenged the previous business paradigm of “shareholder value” in 2019 (the declaration of 181 American CEOs).

Empirical studies show that companies that integrate vital sustainability issues into their business model are more successful. Business potentials such as improving the employer brand, increasing the attractiveness of a company on the financial market,

or merely the vast market potential of sustainable products have spread to the boardrooms and strategy departments. Furthermore, politicians are also proactively shaping a new economic framework. As part of the European Union’s “Green Deal,” more and more companies are being guided toward greater sustainability.

To successfully deal with these “new” stakeholder demands, a “sustainable business transformation” is needed. Successful entrepreneurs are already showing how the classic dichotomy between economic success and sustainable development can be overcome. They are developing integrated management approaches that measure and control the company’s impact to create equal value for all stakeholders along the entire value chain.

Synonyms

Environmental and social viability of solar energy; Financial; Survival of solar energy; Sustainability and renewable energy; Sustainability and solar power; Sustainable development of solar energy

Definition

The word sustainability is derived from Latin and today the term sustainability refers accepting any costs involved in the present as an investment for the future. Another definition refers sustainability as maintaining the use of natural resources with considering the future generation and their needs (Kazmi 2020). This concept, which is mostly used

within the framework of sustainable development, is concerned with the effects that present actions have on the options available in the future and associated with ecological, social, and economic sustainability (Jeronen 2020). The second term, solar energy refers to the freely available and practically inexhaustible energy supply produced by radiation from the Sun.

Introduction

Sustainability highlights human impacts on the natural environment and the resource base known as 3P: people, profit, and planet (Elkington 1998). The term implies the acceptance of any costs involved in the present as an investment for the future (Crowther 2012). Sustainability is a controversial topic because it means different things to different people. Mostly used within the framework of sustainable development, it is concerned with the effects our present actions have on future options. Sustainability has risen to prominence recently among the general community through debates about decreasing carbon footprints while some companies have announced their intentions to achieve carbon neutrality in their production processes.

Due to concerns about climate change and global warming, there is worldwide acceptance about the close connection between a sustainable future and sustainable development, and their connection with sustainable energy sources, which has gained importance in the last 20 years. Today, energy is a central issue globally in nearly every human challenge and opportunity. Access to energy is essential, for example, providing jobs and incomes, climate change, or food production. It is especially important to work toward supplying affordable and clean energy, which is the seventh of 17 Sustainable Development Goals (SDG) as it links with other SDGs.

Today, the sustainable development agenda dominates environmental concerns about climate change. The Paris Agreement, implemented in 2016, is the most powerful current mechanism to

strengthen the global response to this threat. It aims to limit global warming to 1.5 °C to achieve more sustainable and equitable society. One hundred and seventy-five Parties (174 states and the European Union) signed the agreement on the first date it was open for signature, and 10 developing countries had submitted their national adaptation plans to decrease the effect of climate change in their countries (UNCC 2021). The society, business, and even school children are more aware of the threat of global warming. There have been many conferences, employee information seminars, street protests, and even “school strikes,” inspired by 16-year-old Swedish activist Greta Thunberg, which gathered hundreds of thousands of students in more than 100 countries (Murphy 2019).

The Concept of Sustainability and Solar Energy

There is a general acceptance that sustainability is synonymous with sustainable development, which refers to efforts to bridge the divide between economic growth and environmental protection. Sustainability is described as a paradigm for thinking the future in consideration with environmental, societal, and economic aspects of an issue, but sustainable development refers to a holistic approach that ends with sustainability (Jeronen 2013). However, sustainability is a broader term referring to the possibilities of continuing in an unchanged manner or developing in a sustainable way (Hart and Milstein 2003). Sustainable development is focused on the preservation of the natural ecosystems and on the rational use of the natural treasures of the Earth. Thus, the concept is oriented toward upgrading life and environment quality by preserving nature and extending its use with reproduction. The main argument is that uncontrolled and overuse of natural resources damages the ecological balance and leads to ecological disasters. The basic principle of sustainable development is to use those natural resources that we can reproduce. Therefore,

sustainability comprises several aspects: energy consumption, population, agriculture and biodiversity, global warming and contamination, equality in the use of resources, and urbanism. Sustainable development is often discussed as an environmental issue regarding resource depletion or energy consumption, although it is a much broader concept related with economic, environmental, and social policy areas. There are four aspects of sustainability that need to be recognized: **societal influence**, which is the impact of society on organizations; **environmental impact**, which defined “the effect of the actions of the organisation upon its geophysical environment; **organizational culture**, which is defined as relationship between the organization and its internal stakeholders, particularly employees; **finance**, which is referred as providing an adequate return for the level of risk undertaken” (Crowther and Aras 2008, p. 47).

The Industrial Revolution was based on the consumption of great quantities of energy. Energy consumption was used as a measure a country's level of development. Today, however, two centuries later, with the emergence of industry and increased energy consumption, the problem of the quality of environment is becoming as serious as development. The environmental concerns of global warming, climate change, and ozone depletion have raised awareness regarding the use of sustainable energy forms, such as the Sun and wind. Sustainable energy is long-lasting with much less emission of polluting gases. Examples are the Sun, wind, and geothermal energy, which are environmentally friendly, renewable energy forms, compared to classical sources like wood, coal, oil, and water. Today, renewable resources represent less than 1% of total electricity production. The Sun offers the cleanest and the most accessible source of energy as its irradiation is free (Toker 2015). Solar energy comes from the Sun; one star among 400 billion stars in the Milky Way Galaxy, and contains more than 99% of all matter in the Solar system. Its energy is clean and inexhaustible, and can be transformed into other forms of energy: thermal, electric, chemical,

mechanical, etc. Of all the clean technologies, solar energy is the most efficient renewable energy source to reduce global warming.

During the environmental awakening and mass movement, the concept of sustainable development was defined in the declaration of the ministerial conference of the UN Economic Committee for Europe in 1990 in Norway. It was also accepted by the European Union in 1990. The development of new institutions, and establishing new laws and organizational bodies to protect the environment were the next steps in this process. Many national and international conferences have drawn attention to climate change and environmental protection since the 1990s. The main issue at the 1992 UN Rio Conference was the strategy of the sustainable development and its impact on the environment. During the 1997 Kyoto Conference, environmental protection associations agreed to decrease gas emissions, which contributed 5% of the greenhouse effect in 2008–2012 compared to their level of use in 1990 (Britannica 2021). The Brundtland Report in 1987 introduced environmental issues into the sustainable development concept by arguing for “meeting the needs of the present generation without comprising the ability for future generations to meet their own needs” (WCED 1987, p. 41). In business terms, the report showed that the environment is not a limitless pool of natural capital that we can use without liability (Blowfield 2013).

Summary

Sustainability is a complex, interlinked subject that is not restricted to the physical environment. While sustainability was initially assumed to be a fad, economic crises show that being sustainable means to survive. In the 2000s, the “greening” started to morph into “sustainability” and be translated into business jargon, such as the “triple bottom line” and “eco-efficiency,” before diffusing into virtually every major development. Today, concern about sustainability has

become attached to climate change to dominate all industries and the global economy (Bergquist 2017). It has become a mainstream topic in business.

Currently, sustainable development needs bolder actions to ensure the survival of future generations. Using renewable sources and rapid development of clean energy production systems is vital for the future. “The importance of renewable energy will definitely continue to grow in a world, where the demand for energy will be 56% more than today in 2040” (Bloomberg 2013). Energy is the dominant contributor to climate change, accounting for around 60% of total global greenhouse gas emissions. However, the share of renewable energy in final energy consumption reached 17.5% in 2016, with only 55% derived from environmentally friendly, renewable energy forms (UN SDG 2021). Universal access to renewable energy and its efficient use is crucial to creating more sustainable and inclusive communities. Solar energy is the most efficient, renewable, and sustainable source for today and the near future.

Sustainability and Sustainable Development in Real Estate Industry

Saheed Matemilola¹ and Oluwaseun Muraina²

¹Department of Public Law with Reference to the Law of Environment and Planning, Brandenburg University of Technology, Cottbus-Senftenberg, Germany

²Department of Estate Management/Centre for Housing and Sustainable Development, University of Lagos, Lagos, Nigeria

Synonyms

Circular real estate; Eco-friendly building; Green building; Green real estate development; Sustainable property development

Definition

Real estate generally refers to land including the air above it and the ground below it, and any permanent improvements made to or on the land, whether natural or man-made such as water, trees, minerals, buildings, bridges, and other fixed structures and infrastructure components (Chen 2021; Planning Commission 2002). The term is also used to describe the “bundle of rights” associated with the ownership and use of the physical characteristics of space and location (Mettling and Cusic 2019). Real estate can therefore be considered as an immobile and physically tangible product with intangible ownership rights (Kohlhepp and Kohlhepp 2018). Real estate development otherwise referred to as property development is

the process of creating or increasing the value of real estate through carrying out tangible improvements on it (Bulloch and Sullivan 2010). It is a business process that includes activities ranging from acquisition of virgin land and selling off of developed parcels; to renovation of existing building and leasing out to others; and conversion of existing building from one use type to another. Real estate development is a continuous process of reconfiguration and improvement of the built environment to meet the various needs of space (Belayhun 2021; Bromley 2016). Real estate is therefore a core ingredient of the urban environment which in-turn represents a spatial factor of sustainability (Walacik et al. 2020). Thus, it is important to understand sustainable development to adequately delineate the concept of sustainable real estate development. There is arguably innumerable definition of sustainable development, however, the definition put forward by the Brutland Report “... *development that meets the needs of the present without compromising the ability of future generations to meet their own needs*” seems to have gain more prominence. Like many other definitions, this definition promotes the concept of *futurity* and *equity* within and amongst societies in the pursuance of development (Keeping and Shiers 2004).

Introduction

Human developmental goals and aspirations shape the natural, built, and as well as virtual environment through anthropogenic activities. These environments consequently shape the lives and experiences of organisms. Whether it is the clearing of rainforests for agriculture, construction of the world's longest bridge for mobility, or development of 5G network for hyper transmission speed, all these alterations to the environments affects lives in multiple dimensions (Booth et al. 2013). The real estate industry as a big component of the built environment has tremendous bearing on development, chiefly in terms of advancing economic and social growth.

This is particularly crucial for many developing countries where there is usually critical shortage of accommodation especially in the form of residential and commercial properties which forces many citizens to seek alternative in informal shelters (Gunter and Manuel 2016; Mouzoughi et al. 2014).

Globally however, especially in the developed countries, there has been a notable amount of building adaptation from one type of use to another in the last 20 years. This trend in building adaptation is facilitated by the fact that adaptations are typically faster to complete and occupy and often cost less relative to new construction. Also, since the early 2000s, the emerging importance of sustainability has grown significantly in the building industry and adaptation represents a sustainable direction (Wilkinson 2014). Buildings are long-lived products, and according to Lucon et al. (2014), a significant proportion of buildings that will be in use globally by the year 2050 are already in existence. This opinion is also echoed by Kelly (2009) which estimates that 81% of the building stock expected to be in operation in 2050 has already been built and in operation. Other studies have estimated that 87% of the building stocks that the UK will have by 2050 and 89% of the building products that will be in use in Sydney by 2030 are already built (Wilkinson 2014; Matemilola et al. 2018). As a result, there is the need to adapt the existing building stock to ensure high performance through periodic efficiency retrofitting to upgrade facilities and equipment, improve design, and ensure efficient water and energy usage and that overall building systems are performing optimally. Adaptation and reuse of existing buildings will significantly reduce the amount of construction wastes destined for landfills and will reduce the use of raw materials. These approaches are inevitable to evolve a built environment that has the least environmental impact and fosters a more equitable and healthier society (Becqué et al. 2016; Wilkinson and Sayce 2015).

For far too long, profit is the only important goal investors in real estate set-out to achieve but

growing awareness of the finite nature on natural resources, progressive social injustice and trend in climate change have informed the need for clear and comprehensive sustainability program in the industry (Yusoff et al. 2018). The built environment is responsible for the emissions of one-third of the global greenhouse gases (GHG), thus according to UNEP's Buildings and Climate Change report (2009:4), the built environment is significantly critical to the delivery of a cost-effective emission reduction and that nations will struggle to meet their emission reduction targets without a sizable gain from the sector. For the real estate sector to contribute to intergenerational justice, mitigate climate change while ensuring long-term economic viability of business, proactive measures must be taken, world over to integrate and implement sustainability aspects in real estate design, development, and operation (Wilkinson and Sayce 2015; Yusoff et al. 2018).

Real Estate and Sustainability

Since the rise of sustainable development topic to the top of global political agenda, the need for a sustainable means of developing the urban environment in general and the real estate subsector in particular have been identified to be critical to all aspects of sustainability. The real estate development process has significant bearing on material resource and energy consumption, waste generation, and the physical design and impact of urban spaces (Wilkinson and Sayce 2015). Rather than employing resources and strategies that can increase the carbon footprint of a building, sustainable real estate development is therefore considered as the act of assimilating environmental-friendly design, materials, techniques, and technology into the construction process of a building product (Merrill 2021). The goal of sustainable real estate development is to reduce a building's impact on the environment from the design and materials to the daily operations of the building, thus, sustainability in real estate is enhanced when stakeholders in the real

estate industry offer services that aim to sustain the concept of real estate and sustainability (Razali and Adnan 2015). It is therefore pertinent that stakeholders in the property industry and their advisers understand the relevance of sustainability indicators to assess, record, and manage the move towards sustainable development (Keeping and Shiers 2004).

Sustainable growth is impossible without a robust real estate market that offers facilities for all human activities while enhancing the public spaces in cities and towns. The need for appropriate real estate development solutions is prompted by issues with haphazard urban development, energy use, pollution, and climate change, among others. When discussing sustainable real estate, "sustainable development" refers to building a constructed environment that effectively uses resources and considers environmental factors (Kibert 2005). Sustainable development means prioritizing high-caliber initiatives, social diversity, mixed-use buildings, and sustainable structures. According to Choguill (2008), no city will be viable if its constituent elements are not. As a result, it's crucial to start with buildings. Unfortunately, because facilities are one of the leading producers of CO₂ emissions, they negatively influence the environment considerably. It contributes to global warming and the greenhouse effect. For example, over 40% of all energy used in the European Union (EU) nations is used by structures, with residential buildings accounting for around 63% of this total (Balaras et al. 2007).

Indeed, the real estate sector is significantly and increasingly impacting other environmental factors. It consumes the most energy and produces the most CO₂ emissions. Although measuring is complicated, many studies imply that the real estate industry is the most significant contributor to CO₂ emissions.

- Over 40% of the world's energy is consumed by this sector each year.
- Buildings account for 20% of all global greenhouse gas emissions.

- Building CO₂ emissions are anticipated to rise by 56% by 2030.
- By 2030, it is anticipated that the proportionate share of global GHG emissions will increase by 7%.
- Forty percent of raw materials worldwide are used for buildings (3 billion tons annually).
- Building industry is projected to consume 12% of the world's freshwater by 2030.

However, observable disparities within the real estate value chain sub-sectors that have varying degrees of maturity in addressing their environmental and social repercussions are impeding the effectiveness of the real estate industry's sustainability initiatives. But compared to some of its competitors, including engineering and construction or building supplies, the sector lags. Building construction and management, from purchasing and engineering through design and disposal, need an integrated approach. The sustainability results are therefore erratic.

According to Carbon Trust, most investment portfolios typically only include a tiny amount of real estate. However, given that residential and commercial real estate collectively serves as the conduit through which up to 40% of carbon emissions are produced through their development and subsequent use, it is an important asset class for people looking to make environmentally conscious investments (Bissiri et al. 2019). Since many believe that real estate has the most potential to reduce carbon emissions at the lowest cost of any other economic sector, even though it does contribute to the issue of carbon emissions, it also contributes to the solution. Since the environment hosts most human social and economic activities, the real estate industry is increasingly acknowledging the importance of sustainability issues for everyone involved in the creation, use, ownership, and management of the real estate. These issues have also enabled a developing commercial imperative because it is believed to affect how the real estate market functions and the economics of real estate investment. This has made it possible to proactively recognize and address

sustainability concerns (Matemilola and Salami 2020; Turner and Onorato 1999).

Achieving Sustainability in the Real Estate Industry

The World Bank estimates that emissions from the real estate industry must be reduced by up to 36% by the year 2030 if the target of the Paris agreement to limiting global warming to well below 2 °C must be reached (Peiser and Wiegelmann 2020). In a world that is fast evolving and urbanizing, the real estate industry is critically important to reaching the sustainable development targets and stakeholders in the industry; investors, developers, occupiers, experts, and governments must play their roles (RICS 2019). Globally, the real estate industry has become one of the prime targets for governmental legislations and regulations. Nations and cities around the world are now pushing for new policies to help mitigate the environmental implications from the built environment. Thus, new building techniques and practices that can foster conservation and sustainability are now being adopted with the institution of green building schemes such as Building Research Establishment Environmental Assessment Method (BREEAM) in the UK, Leadership in Energy and Environmental Design (LEED) and Energy Star in the US, Deutsche Gesellschaft für Nachhaltiges Bauen (DGNB) in Germany, Comprehensive Assessment System for Built Environment Efficiency CASBEE in Japan, Green Star in Australia, High Quality Environmental standard (HQE) in France, Protocol ITACA (developed by ITACA – the Italian Conference of Regions and Autonomous Provinces) in Italy, and the Sustainable Building Tool (SBTool) in Canada (Peiser and Wiegelmann 2020; Sev 2011; Apanavičienė et al. 2015).

There is a considerable level of misconception about sustainability and environmental protection and many individuals limit the scope of sustainability to the consideration of environmental

aspects of an activity. In fact, green building is sometimes erroneously used synonymously with sustainability (Falkenbach et al. 2020; Matemilola et al. 2019). However, beyond green building schemes, analysis of sustainable real estate is generally considered in the context of building impact on the occupants and workers – such as health impact (micro approach); global impact such as emission generation and resource usage (macro

approach); urban/regional sustainability issues including greenfields and brownfields (meso approach). Ideally, the theoretical basis for sustainability involves environmental-ecologic, social-cultural, and economic-financial dimensions consideration; however, in the real estate practice, it is not as simple. For example, to increase building efficiency (floor-space per land area-density) may be environmentally and

Sustainability and Sustainable Development in Real Estate Industry, Table 1 Real estate sustainability issues

Sustainability dimension	Sustainability issues	Principal objectives
Economic sustainability	Maintenance of high and stable levels of local economic growth and employment I. Improved project delivery II. Increased profitability & productivity	Increased productivity; steady profit growth; employee happiness; supplier satisfaction; and client satisfaction; minimizing defects; reliable and shorter completion times Lower projects costs and improved cost predictability; providing services that are most beneficial to customers and concentrate on expanding client business
Environmental sustainability	Effective protection of the environment I. Avoiding pollution II. Protecting and enhancing biodiversity III. Transport planning	Reducing harmful emissions; preventing noise and dust disturbances through effective site and depot management; minimizing and eliminating waste; preventing pollution-related incidents and environmental law violations Establishing new habitats and enhancing the ecosystem; protection of delicate ecosystems through careful planning and management of construction projects Plan for green transportation for site and business activities
	Prudent use of natural resources I. Improved energy efficiency II. Efficient use of resources	Reduced energy use during corporate operations; energy-efficient depots and facilities Utilize local resources and low-embodied energy materials; design for whole-life costs; minimizing waste through lean design and construction; using products with recycled or sustainable materials; minimizing and managing waste and water
Social sustainability	Social progress which recognizes the needs of everyone I. Respect for staff II. Working with local communities and road users III. Partnership working	Providing efficient training and evaluations, equitable terms and conditions of work, and equal opportunities; a safe, healthy, and favorable work environment; keeping up morale and satisfaction among employees; involvement in decision-making Minimizing local inconvenience; minimizing delays and disruptions in the traffic; creating efficient communication channels; boosting the local economy through supporting local employment and procurement; providing services that improve the neighborhood's surroundings Establishing enduring connections with customers; establishing enduring connections with nearby suppliers; corporate responsibility; providing services that are most beneficial to customers and concentrate on expanding client business

Adapted from Akadiri et al. (2012)

economically sustainable but not socially sustainable (Walacik et al. 2020). Thus, the coverage of sustainability extends beyond green issues, and such additional factors create added value in the measurement of real estate sustainability. Real estate market sustainability can therefore be categorized to varying degrees of sustainability or unsustainability types. Based on Kauko (2017) and as analyzed by Walacik et al. (2020), a sustainable real estate market is attained when maximum environmental sustainability is maintained while ensuring highest economic value and social equity so that the ability of future market participants to meet their own needs is not hampered. The principal sustainability issues associated with real estate is abridged in the Table 1.

Summary

Real estate which includes land and any permanent improvements made to or on it is a core ingredient of the urban environment which in turn represents a spatial factor of sustainability. Sustainable real estate development therefore as a strategic ingredient for achieving sustainable development must be adequately delineated. Since the rise of sustainable development topic to the top of global political agenda, the need for a sustainable means of developing the urban environment in general and the real estate sub-sector in particular have been identified to be critical to all aspects of sustainability. For far too long, the only important goal that real estate investors have set out to accomplish has been making a profit. However, growing awareness of the finite nature on natural resources, progressive social injustice, and trend in climate change have informed the need for clear and comprehensive sustainability program in the industry. Without a robust real estate market that provides facilities for all human activities while increasing the public spaces in cities and towns, sustainable growth is impossible. The need for appropriate real estate development solutions has been motivated by issues with haphazard urban development, energy use, pollution, and climate change,

among others. Globally, the real estate industry has become one of the prime targets for governmental legislations and regulations. The built environment is indeed reported to be responsible for the emissions of one-third of the global greenhouse gases (GHG), thus built environment is significantly critical to the delivery of a cost-effective emission reduction and that nations will struggle to meet their emission reduction targets without a sizable gain from the sector. Nations from all around the world are currently promoting new regulations to assist reduce the environmental effects of the built environment. Thus, with the establishment of green building schemes like BREEAM in the UK, LEED and Energy Star in the USA, DGNB in Germany, CASBEE in Japan, Green Star in Australia and South Africa, and the SBTool in Canada, new building techniques and practices that can foster conservation and sustainability are now being adopted. These tools are evolved to provide a way to quantify a building's environmental effects through assessment of the environmental and resource-efficient performance of a building, optimize building performance, and minimize environmental impacts.

Sustainability and Sustainable Development in the Food Industry

Ruhan Aşkın Uzel
Food Processing Department, Yasar University,
Bornova-Izmir, Turkey

Synonyms

Sustainability in food industry; Sustainable production and sustainable development in food industry

Definition

The term sustainability began to be used as an explicit social, environmental, and economic ideal in the late 1970s and 1980s (Caradonna 2014). It is fundamental to meet vital needs, to use resources effectively, and to conserve the natural balance in order not to exhaust those resources. Although the sustainability approach has been examined in different terms depending on the field in which it is addressed, it essentially characterizes the sustainability approach (Edtmayr et al. 2016). In relation to sustainability, the term sustainable development can be defined as the entire policies pursued in order to increase the welfare and standards of living in a sustainable manner (Diouf 2019). Sustainable development can be applied in many areas of industry. However, the food industry is a good example of a sector in which sustainable development is important. Moreover, increasingly visible threats to the world's eco-system created by traditional methods of production in the sector which adversely affect all living organisms have demonstrated why sustainable development needs to occur. The development of a culture within the food industry which works with nature rather than destroys it has become a necessity. It is critical that good quality raw materials are used, and that by-products and waste materials are handled in an

environmentally sensitive manner. Feedback from the production process is also necessary in improving the technical infrastructure. In this entry, a conceptual analysis of sustainability will be undertaken within the context of the food industry and the position with regard to sustainable development examined.

Introduction

Environmental problems caused by human consumption habits have become important global issues (Laszlo and Cescau 2017). In no particular order of importance, these problems include global warming, reduction in habitable land, overproduction of some foodstuffs, and health problems such as malnutrition (Hughes et al. 2017). Another of these problems, unplanned urbanization, is difficult to predict. One of its consequences is damage to the ecosystem as food has to be produced on less and less fertile land. The other consequence is the waste problem as a result of people's negative behavior in disposal of food waste due to urban overconsumption (Valenzuela and Böhm 2017). Unfortunately, more than half of the world's population lives in cities. However, it is not appropriate to directly link the irregular consumption of resources and the destruction of nature only to urbanization. With conscious consumption habits, people can establish a sustainable environment regardless of their location. In this way, life quality, access to food, and the conservation of nature can be ensured.

Global environmental problems began to emerge at the end of the twentieth century in proportion to the progress of the industrial revolution (Carvalho et al. 2018). In the following century, the industry's dependence on non-renewable energy sources created a situation that requires caution to ensure sustainability (Bowden and Payne 2010).

However, society has started to become aware of the problems regarding the sustainability of life, and some positive responses come from some of the initiatives. Start-ups, non-governmental organizations, and associations,

whose number is increasing day by day, are typical examples of this. In this context, the point that should be considered is that instead of focusing on short-term solutions to problems, people's consumption habits should be managed well in order to reduce the damage to the environment. Therefore, sustainability is a planned process that can achieve this (Caradonna 2014). Although sustainability goes beyond just environmental issues (social and economic dimensions are other related domains), environmental factors need to be kept central to any definition of sustainability (Crist et al. 2017). Therefore, it is possible to define the concept of sustainability as the long-term reproduction of a system in order to sustain itself. When the concept of sustainability is considered in the context of the food industry, it can be defined as bringing sustainability by using awareness and resources effectively in the stages of the supply of raw materials, processing, packaging, logistics, and consumption of food (Krishnan et al. 2020).

This sustainable cycle from raw materials to consumption and even disposal of waste in the food industry is actually similar in other industries. Organizing the production and service activities of all industrial areas within this framework will contribute to the development of the country (Ghafoorpoor et al. 2018). The level of development of a country can be characterized by the sustainability of its environmental, economic, and social dimensions. Such sustainability will manifest itself as one development tool in an efficient cycle (Holden et al. 2017). The food industry is in a highly strategic and functional position in terms of ensuring competitive advantage within the scope of sustainable development policies (Costanza et al. 2016). Hence, within the scope of this chapter, the importance of sustainability in the food industry will be discussed and the principles of sustainable development will be examined in an industrial context.

The Concept of Sustainability

Sustainability in life, the planet, cities, manufacturing, food security, energy, technology,

waste management, etc., has become a frequently encountered concept lately (Sikdar et al. 2017). Despite this, sustainability as an idea is so comprehensive and addresses so many different industrial fields that it can be difficult to give it a precise definition (Moore et al. 2017).

The definition of sustainability has changed over time depending on developments in the economy, politics, and technology (Caradonna 2014). Sustainability as a policy concept has its origin in the Brundtland Report of 1987 (Brundtland 1987). The report focuses on the balance established in a sustainable framework between expectations and limited resources in nature (Kuhlman and Farrington 2010). It can also be used in the sense of leaving future generations a sustainable world with reasonable ecological, economic, and social conditions (Sikdar et al. 2017).

The concept of sustainability is a holistic approach encompassing ecological, economic, and social dimensions (Bastianoni et al. 2019). In addition to a clean natural environment that can renew itself, the concept also encompasses social conditions based on equality and prosperity, and an economic system that considers society and the environment. In other words, while sustainability is often associated only with environmental protection, it also covers the economy and society. Based on the approaches made on sustainability, it can be seen that sustainability is closely related to the concept of development. Development aims at increasing the welfare of individuals (Ukko et al. 2019). Sometimes, the concept of development has been associated with economic growth (Chen et al. 2020). However, nowadays, it has become clear that development cannot be achieved only by economic growth, and many different factors should be taken into consideration (Lee et al. 2016). Therefore, the term sustainable development has become commonplace where, in addition to economic growth, other factors in increasing levels of welfare are being taken into account, such as social equality, the natural environment, gender equality, education, health, and responsible production and consumption (Fig. 1) (Costanza et al. 2016).

Sustainability and Sustainable Development in the Food Industry, Fig. 1 Areas that form the basis of the sustainability concept (Sulewski et al. 2018)

As it is seen from Fig. 1, the sustainability concept treats society, nature, and the economy as intertwined clusters (Edtmayr et al. 2016). Each of these clusters also has a function within itself. Considering the social cluster terms such as life standard, education, community awareness, and equal opportunity comes into account. For example, individuals with low living standards may not have good educational opportunities if they do not have economic opportunities. No matter how high the level of awareness and consciousness is, this situation may not bring what is expected in terms of equal opportunity, and the social side of the concept of sustainability is disrupted (Passani et al. 2016). Considering the second cluster, the environmental cluster, there are concepts of use of natural sources, environmental management, and prevention of pollution. For example, if there is a problem in accessing natural resources, environmental management cannot be done effectively in the waste disposal parameter. Unfortunately, prevention of pollution cannot be achieved effectively as one of the sine qua non principles in environmental management. It is difficult to talk about a successful sustainability in conditions where environmental factors cannot be regulated (Ali and Vladich 2016). In the economic cluster,

the third and the last cluster, the factors of profit, saving, economic growth, research, and development are dominant. Enterprises, including the food industry, aim to make a profit by settling their production lines. Thus, they provide economic growth (Ribeiro et al. 2018). If production is carried out under more prosperous conditions, this will also provide progress in research and development activities, because the business has the power to invest in these activities. This contributes to economic sustainability. The factors mentioned reflect the balance that the three main clusters of sustainability have created within themselves. Hence, each of these clusters is inter-related, so the sustainability of each is interdependent. In other words, if natural resources are consumed in a way that cannot be renewed, the economy cannot be sustained.

At this point, the most important thing to note is that nature is not necessarily in itself the most threatened element under consideration. Individuals have disrupted the ecosystem, but the world has existed for 4.5 billion years and will continue to exist no matter how individuals act. However, the future of humanity is at risk and depends on the ability of individuals to adapt to a sustainable way of life. Therefore, the environment will

survive without economy and social life, while the economy and the social life will not survive the destruction of the environment (Mensah and Casadevall 2019).

The Need for Sustainability: Its Discovery and Progress Through History

As has been noted above, although the concept of sustainability is most often used in the context of the environment, this perspective can be used in many areas such as food, chemistry, pharmacology, construction, textile, technology, energy, culinary arts, etc. (Boye and Arcand 2013). In 1972, the first global assessment of the socio-economic environment was approved at the United Nations Conference on Human Environment in Stockholm (Bastianoni et al. 2019). The aim was to prepare for the future and to avoid possible environmental threats. Thus, environmental sanctions were agreed and enforced for the first time (Klarin 2018). Eco-development was also emphasized at the Stockholm Conference. Accordingly, it has been essential that economic development be carried out without disturbing the balance of nature and without harming the environment (Ali and Vladich 2016). Prior to this conference, little or no attention was paid to the development of international environmental law. Until this period, it has been observed that the first practices regarding the protection of the environment were aimed at the protection of natural life and rivers. Since then, a structure for cooperation within the United Nations (UN) has been established by signing many regional and universal agreements regarding different environmental problems (Kayhan 2013). For the first time, with the Stockholm Conference, environmental problems started to be addressed at a global level and with wide participation. This conference led to the rapid development of international environmental law and the establishment of the United Nations Environment Programme (UNEP) (Kaniaru 2016). Hence, ensuring the implementation of the concept of sustainability on behalf of the environment is considered very important. The main purpose of

the United Nations declaration is to ensure that nature contributes to the development of humanity without being damaged.

As mentioned in the previous section, sustainability uses environmentally friendly technologies primarily to ensure the balance of nature and the balance of the population in all its activities and plannings (Kamani et al. 2019). In order to realize the concept of sustainability, it is necessary to focus on economic, environmental, and social sustainability altogether. One of the important tools in making this happen is sustainable development (Munasinghe 2009). The sustainable development approach determines the common denominator in the economic and social development goals of countries as “sustainability” (Klarin 2018).

To summarize, the history of sustainability dates back more than 40 years (Nocca 2017). Today, the sustainability concept is used not only for nature but also in many different fields (Caradonna 2014). For example, many companies use this concept to create a sustainability index. There are many different types of sustainability index such as the data about the financial and economic performance of companies forming the Corporate Sustainability Index (ISE)’s “theoretical portfolio” (Liu et al. 2018). In other words, the sustainability index considers the economic and social benefit of remanufacturing and problems arising from environmental pollution. It gives information about the value of companies and is also designed to provide information to investors at the same time (Edtmayr et al. 2016). Many of them are used to measure the companies’ performance around the world and to compare their performance with others depending on some parameters.

The main parameters here are the ones that are critical elements for sustainability. Some of them are environment, biodiversity, climate change, human rights, supply chain management, health and safety, etc. (Edtmayr et al. 2016). Apart from this, there are many projects that are examples of interdisciplinary approaches to sustainability such as sustainability in business and industry, sustainability in information and communication industry, sustainability in governance, sustainability in

food production, and sustainability in agriculture, etc. For example, the waste material formed after the process is as important as the raw material in food production. For example, in addition to the product produced in the beverage industry, many materials such as shell and pulp which will come out as waste. After processing, these waste products can be used as a raw material for the feed industry or as a fertilizer material, or even reused as decoration material for food, for example, following drying or spray-drying processes (Eswari et al. 2020). This process is an example of circular economy in an interdisciplinary sense in the theme of sustainability in the fields of food, chemistry, agriculture, economy, technology, and environment (Chen et al. 2020).

Sustainability in the Food Industry

The world's population is expected to exceed 8 billion by 2030 (Giles-Corti et al. 2016). To meet the nutritional needs of the world's population, the production of sustainable, safe, and healthy food and the improvement of the quality of life are an important responsibility for the food industry. At the same time, the industry must respond to the need for such things as nutritious and personalized foods and adapt itself to developments in technology.

For this reason, sustainability in food is important in terms of meeting the natural nutritional needs of the next generations in society. A sustainable approach to food production is one of the most critical issues for the sector in the development of strategic solutions. It involves activities in the following areas (Dwivedi et al. 2017):

- Efficient use of energy
- Responsible management of water and wastewater
- Optimizing resource usage
- Responsible packaging
- Preventing greenhouse gas emissions

Water is among the most important aspects of sustainability in food. Both the needs of the growing global population for water and the needs of

the agricultural sector cause water resources to deplete rapidly (Nouri et al. 2019). Moreover, water is disappearing due to rapid and irregular urbanization (Bhattarai and Budd 2019). In order to prevent this, there are a number of important initiatives that need to be implemented by the food industry, by local producers, and by society, as outlined below.

Groundwater drawn without planning and excessively is a major factor in droughts (Aydın and Tuna 2018). For example, problems of finding clean water are encountered in many regions due to the excessive operation of deep boreholes drilled without planning (Rogers and Chung 2017). Another example of this situation is the withdrawal of groundwater as a result of unplanned use of groundwater and the formation of sinkholes as a result of karstification in limestone (Goudie 2018). If society tends to consume natural resources immediately and unconsciously, these resources will be depleted immediately. This, in turn, leads to the notion of being a society based on consumption rather than production, without considering future generations (Cattaneo et al. 2020). For this reason, among the first steps to be taken for sustainability is to purchase food strictly on the basis of need, considering available capacity. Another point that needs to be handled carefully in the conscious use of resources is the issue of waste (Cattaneo et al. 2020). When determinations on waste are taken into consideration solely on the basis of the social dimension, it can be understood that the issue is an evolving one. For example, at an individual level, the disposal of 100 grams of bread is rather immaterial. However, when the amount of bread thrown into the garbage every day at a national or international level is calculated (enough to feed the population of Africa for 2 days), the magnitude of waste and the danger of malnutrition in the future are understood. In more than half of the due diligence studies on sustainability in the food sector, the importance of sustainable industrial and community awareness is noted (Passani et al. 2016).

In addition to the effective use of resources and the prevention of unnecessary waste, another factor affecting sustainability in the food industry is the implementation of sustainable packaging

technology. When the concept of sustainability is examined in terms of food packaging, the following points can be made (Helanto et al. 2019):

- It must be cost-effective and meet market performance criteria.
- It must be compatible with consumer expectations.
- It must be produced from recyclable or biodegradable materials and thus be efficiently recyclable.

Sustainable food packaging technology is a green process (Wikström et al. 2019). Another application area that can be given to the green process in the food industry is green supply chain (Yan et al. 2016). The green supply chain is defined as the process of incorporating environmental criteria or concerns into organizational purchasing decisions and long-term relationships with suppliers (Krishnan et al. 2020). It is possible to consider a green supply chain as being at the intersection of the economic interests of enterprises and environmental sustainability. The importance of a green supply chain is increasing as natural resources are rapidly depleted and the need for economic sustainability grows. Hence, a green supply chain is a new paradigm that combines product development and environmentally friendly product or service production strategies. In this paradigm, the aim is to cleanse the supply chain of negative externalities arising from production such as lack of coordination, shortage of supply, low prices, adverse natural events (excessive rainfall, floods, and storms), and decrease in yields per acre (Çalık 2019). The objectives of a green supply chain can be listed as follows (Liu et al. 2018):

- To make the best use of limited natural resources
- To minimize energy consumption
- To prevent environmental damage and to look for alternatives to reduce environmental pollution caused by industry
- To create recycling awareness
- To ensure sustainable development

The listed objectives of a green supply chain will provide support to food industry companies in ensuring environmental and economic sustainability. It also plays an important role in enabling efficient resource use and in ensuring ecological efficiency. Activities covered by green supply chain management, such as green purchasing, green production, green marketing, green packaging, and reverse logistics, are among the pioneering sustainability topics in the food industry (Fig. 2).

In summary, food is of critical importance in maintaining healthy and good quality lifestyles for the next generation. Hence, society needs to adopt the concept of food sustainability in order to learn about sustainable nutrition and therefore sustainable living, and to avoid wasteful consumption.

Sustainable Development

The concept of sustainable development has its roots in the 1980 World Conservation Strategy report by the International Union for Conservation of Nature and Natural Resources (IUCN) (International Union for Conservation of Nature & World Wildlife Fund 1980). The term sustainable development has been expressed with various definitions at different times (Ramcilovic-Suominen and Pülzl 2018). The publication in 1987 of “Our Common Future” provided one of the most common definitions of sustainable development as development that “meets the needs of the present without compromising the ability of future generations to meet their own needs” (Olawumi and Chan 2018). The general acceptance of this concept and its widespread use are noted by the World Environment and Development Commission’s (1987) in its report entitled “Our Common Future” (Buhr 2007). In this report, sustainable development is defined as the development that meets today’s needs without compromising the ability of future generations to meet their own needs.

Since the concept of sustainable development was first proposed, it has been redefined many times, causing the concept to become unclear.

Sustainability and Sustainable Development in the Food Industry, Fig. 2 Components of green supply chain management (Yan et al. 2016)

Sustainability and Sustainable Development in the Food Industry, Fig. 3 Sustainable development triangle (Munasinghe 2019)

Moreover, the respective definitions generally reflect the academic branches in which it is being used. While economists often tend to emphasize the need to maintain a certain level of living standards, ecologists are interested in biodiversity and ecological flexibility, while sociologists prioritize the need to preserve sociological ties and interrelations within communities (Diouf

2019). In the food industry, the concept of sustainable development is considered as an approach in which postprocess waste management becomes sustainable and consumption-conscious in line with the efficient use of food resources (Notarnicola et al. 2012). Figure 3 schematizes the key elements of sustainable development and the links

between them. Each concept in the corners of the triangle has its own driving forces and targets around it. While the economy is mainly focused on increasing human welfare by increasing the consumption of goods and services, the environmental area is focused on maintaining the integrity and flexibility of ecosystems. The social area emphasizes the enrichment and strengthening of human relations, as well as the achievement of individual and group goals.

The Importance of Sustainable Development in the Food Sector

In the future, the world will struggle with climate change, environmental transformation, and population growth (Hughes et al. 2017). All main and subsectors have different responsibilities both

generally and in the food industry specifically. Therefore, governments, businesses, and consumers should be part of this effort to create a sustainable system and thus achieve sustainable development goals. Food companies will need to develop exemplary practices in the following areas:

- Reformulation of products
- Minimal approach in package design
- Supplier relations
- Creating production standards
- Informing consumers
- Using resources efficiently

Nevertheless, various challenges may arise in trying to reach a fairer, healthier, and environmentally sustainable food system (Table 1).

The challenges mentioned in Table 1 may in fact be interpreted as the cause of problems to be

Sustainability and Sustainable Development in the Food Industry, Table 1 Challenges for sustainable development activities in food industry (Teixeira 2018; Şenocak and Mohan Bursalı 2018)

Challenges	Findings/Causes	Suggestions
Inadequate demand Issues with meeting demand supply	Loss of consumer purchasing power Inadequate capacity of the sector to meet demand or not being organized for production Increasing demand of consumers for sustainable food consumption specific to the product	The working principle of the food market mechanism can be examined Resource management can be done effectively for sustainable production For low-income consumers, price reductions can be made in some product segments Solutions can be developed for individuals to have a healthy and affordable diets (Johnson-Down et al. 2019)
Operational business challenges	Performance evaluations using simple documentation techniques Performance measurements that are not made at appropriate time intervals Inefficiency in operational processes Lack of long-term return on investment Excessive or unused capacity Inconsistent execution of operational processes Lack of leadership and innovation	New business models can be developed Efficient motivation tools can be created for businesses to reach short-term goals Investors can be trained or encouraged to anticipate the cause of environmental problems and to deal with them in sustainable ways (Bastianoni et al. 2019)
Lack of governmental encouragement, leadership, or guidance	Inadequate enterprises and entrepreneurship Long authorization/approval period for the implementation of innovative approaches in food production and R&D activities	Food enterprises can be encouraged and can be guided by government policy to use sustainable food resources Opportunities can be given to business and society to develop sustainable products and services within the scope of sustainable development principles (Messerli et al. 2019)

dealt with in the food industry. Examples of other problems created by the food industry:

Resource and waste management: Effective use of resources is a requirement in the food industry to minimize environmental damage. The food industry can sometimes be a major threat to the environment since special processes are required to eliminate solid wastes and water-miscible waste (Ferronato and Torretta 2019). There are, of course, environmentally sustainable measures that can be taken in this regard. Efforts can be made to recover by-products that are formed so they can be recycled (Boye and Arcand 2013). For example, some food by-products can be used for animal feed or fertilizer production. In addition, cogeneration applications in the food industry can be given as an example in this context. Cogeneration is the production of energy from the same system in both electrical and heat forms, and it is more economical than producing both forms of energy individually in separate places (Bianco et al. 2016). Any branch of industry that needs constant hot air for drying or heating can benefit from cogeneration plants. Some industries that need large amounts of cold air or water can benefit from absorption chillers, such as food-freezing plants, refrigeration plants, or large cold stores for the preservation of foods such as meat, fish, chicken, or vegetables. This application contributes to increasing price efficiency and recycling of wastes by using biological wastes as well (Bianco et al. 2016).

Energy use: Energy resources such as gas, electricity, coal, and oil are used in the food industry, mainly for cooling and heating operations. Energy use to produce food products, chemicals, cars, etc., should be reduced as much as necessary, and accumulated gases in the atmosphere should be controlled (Bowden and Payne 2010).

Water use: The water used in food production should be hygienic (Hampikyan et al. 2017). The use of hygienic water enables the consumer to access clean food and the food producer to produce safe food. However, water consumption in the food industry is significant and can be excessive owing to being used both before and during food processing (Faille et al. 2018).

Packaging: The food industry is an area where packaging is used intensively (Wikström et al. 2019). Some types of packaging materials are not biodegradable and cause environmental pollution. Factors such as the shape and size of the food package are also some of the parameters that are important within the scope of the environmental pollution (Fadare et al. 2020). For example, if the packaging material is slightly larger than it should be, it will cause storage space loss, logistical problems, and consequently higher transportation costs. If transportation frequency increases, it will lead to an increase in energy consumption and in operational costs. For example, before designing a storage facility in a food business, it is necessary to master the characteristics and quantity of the food to be processed. The design of this part should be at a level to facilitate the entry and exit of the food product. In this way, the unique physical handling features and movement regularity, order frequency, and speed of transportation of food products are evaluated. At the same time, a good layout reduces labor cost and increases replacement efficiency and error-free order rate. Therefore, locations that are fixed and variable should be well-known (Jagtap et al. 2019).

At the UN Sustainable Development Summit, 2030, Sustainable Development Goals were adopted by 193 countries (Fig. 4) (Gil et al. 2019). Out of a total of 17 targets, 8 were identified based on the challenges outlined in Table 1 above as important issues in food/related areas within the scope of sustainable development. The sustainable development goals stated in Fig. 4 can be summarized in terms of goals and objectives as follows (Darıcı and Canbolat 2019):

- Goal 1. To end poverty of all kinds, wherever it happens
- Goal 2. To end hunger, ensure food security, improve nutritional opportunities and support sustainable agriculture
- Goal 3. To ensure a healthy life for people and the welfare of everyone at all ages

Sustainability and Sustainable Development in the Food Industry, Fig. 4 Sustainable development goals. (Source: <https://www.un.org/en/>)

- Goal 4. Provide all-encompassing and equally high-quality education and provide lifelong education for all
 - Goal 5. To ensure gender equality and strengthening the social standing of women and girls
 - Goal 6. To guarantee access to water and sanitation for all and the sustainable management of water and sanitation
 - Goal 7. To provide accessible, reliable, sustainable and modern energy for all
 - Goal 8. To ensure sustainable and inclusive economic development, to provide full and productive employment and decent jobs
 - Goal 9. To build durable infrastructure, promoting sustainable and inclusive industrialization and new inventions
 - Goal 10. To reduce inequalities within and between countries
 - Goal 11. To make cities and human settlements embracing everyone, safe, strong and sustainable
 - Goal 12. To ensure sustainable consumption and production
 - Goal 13. To take urgent steps to combat climate change and its effects
 - Goal 14. To protect and sustainably use the oceans, seas and marine resources for sustainable development
 - Goal 15. To protect, restore and ensure sustainable use of terrestrial ecosystems, ensure sustainable use of forests, combat desertification, stop and reverse the loss of productivity of soils and stop biodiversity loss
 - Goal 16. To encourage peaceful and inclusive societies for sustainable development, ensure access to justice for all, and build effective, accountable and inclusive institutions at all levels
 - Goal 17. To strengthen the implementation tools of global partnership for sustainable development and revitalize global partnership
- In addition, it should be noted that sustainable development cannot be evaluated independently from the cultural structure of society (Munasinghe 2009). For example, the food industry should be examined as to its provision of healthy and safe nutrition taking the norms and practices of society into account. Therefore, it is an indispensable tool

to keep society and industry in a sustainable cycle (Carvalho et al. 2018).

Summary

The concept of sustainability is relevant to many areas of the food industry. While it has added value in previous periods, it has now become an increasingly important parameter for the continuity of today's food enterprises. To be successful, the industry needs to fulfill a number of requirements to adapt to sustainable development. The first is the adoption of new technologies based on sustainability, and the development of relevant strategies to use resources effectively in order to apply those new technologies. "Digitalization" applications can be given as an example of one of the most widely known new technologies used (Gbadegeshin 2019). Thanks to digital applications, all processes from raw material supply to consumption can be controlled easily from the field to the fork. As a result of dynamic developments in the digital field, the food industry can be set up to meet both the vital needs of consumers while at the same time satisfying their more emotional desires. Second is sustainability in the evaluation of new technologies primarily for the structuring of legislation and the promotion of university-industry-cooperation projects. The last one is to increase the number of reliable scientific studies considering topics such as climate change, efficient use of energy, supply chain management, food security, and food production modeling and to examine the effects of these factors on food products. When these requirements are met by the food industry, environmental sensitivity will develop, thereby raising the welfare level of society and making production and consumption possible within a framework of sustainability (Popp et al. 2014).

Sustainability and Vulnerability

Antonio Castrofino

Unitelma Sapienza University, Rome, Italy

Definition

Vulnerability is not an easily definable concept like the debate on the studies revealed in this regard. Everything within the concept of “environmental sustainability” is certainly to be understood as the search for predictable and uncertain factors, which presents a risk and leads to damage to people and places and which “reduces the ability to respond to threats” (Cutter 2003). The vulnerability is composed of susceptibility to damage, exposure, sensitivity, and adaptability. For this reason, the vulnerability could be defined

as: “the forward-looking probability of experiencing a loss in the future relative to some benchmark of welfare ... caused by uncertain events” or the “continuous forward-looking state of outcomes” (Alwang et al. 2001).

Introduction

The current climate changes pose many questions about the future of our planet and the life that dwells on it. The rise in temperatures due to the greenhouse effect, caused by the emissions of climate-changing gases produced by man, from the use of fossil fuels, is already leading to important and dangerous changes within the delicate earth climate system. Extreme weather events are increasingly frequent and always have a greater intensity. Many species, like humans, run the risk of not being able to continue to survive under the same conditions as some centuries ago. Some of these species will not be able to adapt in time because of the rapidity of change, and they will become extinct. Many other species have already become extinct. The ability of man to stop and imagine a sustainable development model will be essential to find a solution to all this.

Much hope had been placed in COP21 in Paris (https://ec.europa.eu/clima/policies/international/negotiations/paris_en) where the hope of awareness of the human factor in the environmental crisis involving the whole planet was placed. The goal was then to contain the rise in temperatures within the 1.5 °C limit by the end of the century, build resilience, and reduce vulnerability. It is well-known that the indigenous and the poorest will be at the highest risk of becoming vulnerable. At COP24 in Katowice, Poland, a “rule book” is defined to implement the Paris agreement in the hope of reducing greenhouse gas emissions as quickly as possible and curbing this climate crisis.

Vulnerability, Sustainability and Climate Change

Vulnerability scholars have focused on the impact of climate change within human societies. From

the studies of the 1990s of the last century to the present, the research effort by academics, institutions, and governments has been important. Politically, the vulnerability is mentioned in the original UNFCCC text. Over time, however, many doubts have been raised about the vulnerability analysis models based only on climate change, and many scholars have begun to transfer their attention to the concept of resilience, arguing that it is more solid in capturing socio-ecological dynamics.

The vulnerability, however, can be studied through the study of biophysical elements taking into consideration the natural sciences or through the study of social vulnerability (poverty, social inequalities) or the analysis of elements of both.

The interaction between natural sciences and social sciences means that vulnerability does not exhaust its field of research solely to the climatic field but is enriched by socioeconomic studies that affect different spatiotemporal planes and together with system dynamics that make the vulnerability not immobile over time but evolving.

Community studies try to understand how human and biophysical stresses together affect the vulnerability of some territories. Although studies focus very often on the action of globality and not on the action of the local community and the interaction between it and other external actions, local action is what is wished for by most climate scholars to achieve results significant globally.

The association with climate change means that the concept of vulnerability most often takes on a negative meaning. The communities that are associated with them in the imaginary become “passive victims” of harmful events and their difficult forecast. This meaning, if coupled with the indigenous and poorer populations, means that they are defined as disadvantaged with respect to a more general concept of progress without, however, associating this meaning with an analysis that takes into consideration a profound research into the causes that lead to risk factor and the susceptibility of damages: exclusion factors,

marginalization, difficulty accessing education, and social inequality.

Often such damages are associated with extreme meteorological events, which are in strong growth compared to the past and are accompanied by episodes of heavy rainfall (which often cause floods, landslides) and periods of severe drought. The impact of such extreme situations can only have a strong social repercussion. Cities, as well as rural areas, often remain deeply damaged by such events as they suffer from poor historical planning that takes these events into account.

Suffice it to say that the extreme rainfall associated with soil sealing in our cities too often gives rise to easy flooding which, in addition to paralyzing mobility, seriously endangers the lives of citizens themselves. Also for this reason the vulnerability can also be read as a food security key (Alwang et al. 2001).

In rural areas, where agricultural activity is more developed, the communities placed in conditions of climatic stress risk generating damage caused by heat waves, which lead to drought, and by strong and abundant rainfall (and even by meteorological events) more extreme like the strong and sudden hailstorms that could destroy the harvest. If the fruit plants are damaged or the soil becomes unusable because there are no nutrients, the economic-social repercussions become very strong.

Uncultivated and free areas live in a further state of danger. The undergrowth, often in a state of complete abandonment, saw the increase in fires and consequent damage to vegetation. Moreover the strong work of deforestation, especially in the hills and mountains, has meant that these places were increasingly subject to the danger of landslides because, due to the absence of the roots of the trees, the abundance of rains, not finding obstacles, leads the land downstream, putting at risk, in addition to nature, small and large population centers. This is why we talk about hydrogeological risk and the safety of the territories because vulnerability to extreme weather events is likely to bring entire communities to their knees (Monteleone and Sabatino 2014). The morphological

knowledge of the territories, of the geological composition, of the hydrology, and of the historical study of what happened in the past in a given territory are fundamental to face a conflict of future risks. Bioengineering after a careful analysis of areas and territories can play a very important role in planning safety interventions.

An even more important role in seeking solutions to combat environmental vulnerability is assigned to actions and political choices that must favor processes of greater adaptation and environmental mitigation. Deforestation, crops, and intensive livestock are seriously endangering our planet and are not part of the idea of sustainable development (Brown 2009). Intensive crops severely damage the soil, depriving it of nutrients very quickly and making it much a rider and subject to erosion, compaction, sealing, and salinization. At the same time, the choice of seeds that guarantee a strong yield (often GMO), which are then protected with pesticides, often leads to intensive agriculture that is not based on the need for an ecological system to have a biological diversity of products. This absence of biodiversity makes these territories, and the communities that live and work with them, vulnerable should a risk agent (banana crisis) arise.

Key Issues

There is the need to develop an integrated and multidisciplinary action capable of analyzing vulnerable areas starting from the single local realities. In this way it should be possible to assess which kinds of risk the environment and society are exposed to, thus adopting safety and development plans.

Future Directions

Identifying elements of vulnerability soon will mean investigating within environmental and social contexts and trying to develop adaptation, financing, and governance strategies capable of

reducing the risk of damage. Important places of artistic, historical, and cultural interest built in areas of high hydrogeological risk within small and medium urban centers will also be in danger.

This is also why political actions in recent years have not taken into proper consideration the problem of vulnerability in their choices.

Developing overall action frameworks will mean adopting tools that, coming from different disciplines, can develop and fully cover the vulnerability situation over time (Ford et al. 2018). Quantitative climatic modeling and social modeling are too often observed unrelated to each other, but the real objective must be to be able to integrate them together to be able to harmonize a thought and a plan of action, including a political one, that can bring harmony between human and environment.

Summary

Ongoing climate change raises many questions about the future of life on our planet. Droughts, floods, heat waves, and extreme weather events, together with social problems such as poverty, put entire populations in a situation of strong vulnerability. The poorest and most humble populations in the world are the ones most affected by the unpredictability and violence that characterize climate change. Securing territories from hydrogeological risk, fighting deforestation and desertification, adequately treating rural areas, through climate change mitigation and adaptation plans together with social reforms and the use of new technologies, with the support of specialists from different disciplines, it will be essential to be able to create a development that is truly sustainable.

Sustainability as a Management Approach

René Schmidpeter¹ and Christophe Funk²

[Sustainable management](#)

Definitions

Studies show that sustainability is gaining importance in society and companies. In terms of the economic side, sustainable management must be integrated into the company. How can sustainability be used as a management approach?

Based on a Purpose and the associated Values, a sustainable management system can be integrated into a company's DNA. In this way, the

corporate strategy changes from within. Further on, sustainable innovations are promoted in this way, changing the market and enabling competitive advantages. In the same way, value creation takes place. Once the company has adopted sustainable management at its core, it also positively affects its impact on society and stakeholders. This happens through the company's interactions through the different departments that are in contact with the corporate environment.

Structure of Sustainable Management

At the heart of sustainable management is the integrative idea. Sustainability must be implemented based on every company, and must be part of the corporate DNA. To achieve this integration, the trade-off thinking between sustainability and profit must first be overcome. In this way, sustainability management becomes obsolete and is replaced by sustainable management, which is implemented, for example, in marketing, controlling, HRM, etc. Sustainability is, therefore, not an add-on but a part of the company's values. Therefore, it should not be seen as a cost item but rather as increasing profitability by avoiding negative impact and/or generating positive impact. Only if this idea is the central starting point can an impact be generated with corporate strategy, innovations, and value creation that positively affects the company, stakeholders, and society (Fig. 1).

This transformation of the company can also be illustrated using Michael Porter's classic model of shared value. He stated that companies could build a unique selling proposition (USP) with procurement, production, marketing, sales, and customer service. However, this is becoming increasingly difficult due to current circumstances such as the aftermath of the Covid-19 pandemic, financial crises, environmental disasters, and digitalization and artificial intelligence. For example, production in different parts of the world is influenced by the environment. On the other side, marketing and sales are influenced and standardized by algorithms. It is becoming more

challenging to stand out from the competition and develop a USP through these factors. Porter stated that the factors of leadership management, compliance and business law, product development/research, and finance, HR, and controlling are only secondary in a company because all companies conduct these in the same way. However, this is the difference in the approach of sustainable management. Procurement, Production, Marketing, Sales, and Customer Service are all carried out in the same way. However, the USP is formed by other factors, such as the leadership style, how the controlling system is set up (e.g., through non-financial key performance indices), how the company focuses on research and development, and how the workforce is treated. In this way, the thought process in a company also changes. For example, sustainable values embedded in these formerly secondary factors come to the forefront, thereby changing how a company is managed. This ensures that the understanding of sustainability emerges from within and is not imposed from the outside.

M3TRIX Modell for Sustainable Business Transformation

Sustainability's critical factor as a Management Approach is that a distinction is made between sustainable management and traditional management. The traditional understanding of management refers primarily to efficiency – that is, the relationship between input and output. A certain output (e.g., sales, produced goods, profit) should be increased. In the same process, the input (e.g., social capital, human capital, and financial capital) should be reduced. So far, this method has also worked well, but the economy is facing a major transformation due to an ecological and social transformation. In this transformation, it is necessary to consider not only efficacy but also effectiveness. The factors, outcome, and impact have to be integrated into the corporate strategy. Indeed, studies have shown that companies without positive impact would be less profitable, generate less revenue, and become unattractive to

Sustainability as a Management Approach, Fig. 1 The holistic system of sustainable management (according to Schmidpeter)

Sustainability as a Management Approach, Fig. 2 The IOOI model according to the M3TRIX Institute

investors due to the growing investment risk (Oekom 2018; Whelan and Fink 2016; Winston 2019). Thus, companies are increasingly questioning their existence and role in society and want to avoid negative impact, or create positive impact (e.g., social or environmental impact)

for their environment, thus integrating a purpose for doing business into the corporate strategy. To achieve the desired impact, however, a new outcome (impact at target group level) is needed. Once this cycle has been established, this model's efficiency can be increased through new business management measures and/or sustainable innovations.

To best implement this model, companies must think about the future from the present. "What strategic changes need to be made today to achieve the desired impact in the future." (Fig. 2)

Example of the Model

An automotive manufacturer wants to rethink its impact and develop a Purpose for its own business. The company's impact relates to reducing CO₂ emissions from cars and creating better air quality for flora and fauna (Impact). To achieve this goal, the automotive company will build a sharing economy platform. To do this, it will use capital in the form of human, social, and financial capital (Input) to produce its various alternative fuel automobiles and the platform (Output) to generate the desired impact.

Summary

Instead of having an isolated Sustainability Management department business enterprises integrate Sustainability widely in all different management functions. Thereby Sustainability becomes not only part of the strategic management but is part of all management decisions and processes across the firm. This is the base for a new. On this base a new management paradigm emerges in business administration and management science which defines a new role of business in society. This new management paradigm overcomes the old trade off thinking between profit and sustainability. This new management approach defines business as an essential part of the solution rather than the problem to the current social and ecological challenges.

Introduction and Definition

Sustainability education is education approach that aims to develop students, schools, and communities with the values and the motivation to take action for sustainability, in their personal lives, within their community and at a global scale, now and in the future. Sustainability Education for Sustainable Development is a common term used to describe education (ESD). Future-focused, sustainability education puts an emphasis on preserving the environment and fostering a more ecologically and socially equitable society via responsible conduct. Taking measures to promote more sustainable lifestyles necessitates taking into account the interconnection of the environmental, social, cultural, and economic systems (ACARA 2015). It enables

all individuals to acquire the knowledge, abilities, attitudes, and values required to build a sustainable future. Assessment of historical practices, evaluation of scientific and technical advancements, and fair assessments based on anticipated future implications on the economy, society, and environment are all necessary components of sustainability education. Giving people the knowledge, abilities, and drive to organize and manage change toward sustainability within a company, sector of the economy, or community is part of education for sustainability. People who are educated about sustainability are encouraged to visualize a variety of sustainable futures.

What Is Sustainability Education?

The goal of sustainability education is to increase students' awareness and knowledge of environmental issues, as well as to help them become better thinkers, innovators, and problem solvers who can help their communities adopt more sustainable lifestyles. Education for sustainability is based on a broad definition of education and learning that embraces individuals of all ages, backgrounds, and stages of life and that occurs in official and informal learning environments, such as classrooms, workplaces, families, and communities. The goal of education for sustainability is to provide people the tools they need to comprehend how the political, social, and economic systems are interconnected. It promotes community involvement in which all of the interested parties carefully consider what they want their kids to understand, practice, and value when they graduate from the formal educational system. Every community is thus urged to make an effort to anticipate both the short-term and long-term social, economic, and environmental conditions. Key sustainable development topics like climate change, disaster risk reduction, biodiversity, poverty reduction, and sustainable consumerism are made available to teaching and learning through education for sustainable development. At all stages of formal education and training, as well as in nonformal and informal learning,

sustainability education is crucial for achieving a sustainable society.

Education Issues, Sustainability Issues, and Resolution

Regardless of the fact that improving education is necessary for achieving sustainability, progress has been very slow worldwide. There are several causes for this lack of development, but sometimes it is due to a lack of comprehension or eyesight. Because they are entangled with conflicting and frequently irreconcilable values, interests, and knowledge claims, sustainability issues are complicated, unclear, and hotly debated. Others blame a lack of finance or policy. In light of the rising social expectations, the performance of the global educational systems is already being scrutinized. One current worldwide issue that might lead to educational change in many countries is economic security. Environmental problems like pollution, climate change, environmental degradation, and resource depletion have had an adverse effect on both economic growth and environmental health. As a result, greenhouse gases have had an effect on the environment. The necessity for sustainable development is a result of all these causes. It can harm the ecosystem irreparably if left unchecked. Through goals adoption, the current widespread acceptance of educational resolutions will enhance sustainability education. Additionally, advocates of sustainable education should resist overworked facilities that might have an impact on the learning environment.

Awareness and Creativity

Fundamental universal awareness was adopted for the new millennium by the General Assembly of the United Nations and includes tolerance, freedom, solidarity, respect for nature, equality, and shared responsibility (Leiserowitz 2006). The public and the educational community need to become more aware of the necessity of reorienting education in order to attain

sustainability. Partnerships are a key component of education for sustainability because they help create networks, foster relationships, and enhance communication among various community sectors. Attempts to identify crucial connections between education and more sustainable practices are vital to raising awareness. The statement established a series of more precise objectives (17 SDGs) linked to five pillars: planet, people, peace, prosperity, and partnership, in order to transfer this mutual awareness into actions. Awareness, reflection, and critical thinking in sustainability can be fostered by art and creativity. There is an increased awareness of business and academic research toward creative thinking. However, the investigation of its uptake by industry is still limited. Consciousness of the relevance of sustainability to their lives and the environment is important. Understanding creativity as a tactic to increase the learning capacity of students' passive activities is highly encouraged. Everyone should be aware that creativity is a valuable quality that everyone should possess and may exercise collectively. It is better to buy reusable items instead of disposables like paper towels, bottles, and bags made of plastic, start recycling and composting to reduce the amount of waste we produce, eat organic and pesticide-free food, support regional businesses and farmers, and start a communal garden. Additionally, innovative processes and products can be designed to encourage sustainable behavior or offer pro-sustainability solutions (Brem and Puente-Díaz 2020). Awareness on health status through education for sustainability by creating education campaigns on vaccination, clean water, and abstinence from alcoholism and drugs, which are simple concepts to sustainable developments. Compared to single-message public education programs, the success of sustainability education will require significantly more time and be more expensive. The idea of sustainability must be considered as a thought and action process toward goals that cannot be entirely attained but propel societies toward improvement and development (Williams et al. 2017). There are several studies on creative training or sustainability education. Studies combining these two topics, however, are uncommon.

Participation in creative activities or creativity training for sustainability education has been found to positively impact learning motivation, working effects, self-concept, confidence, subjective well-being, resilience, and the positive psychology of learners (Jindal-Snape et al. 2013; Sellman 2012; Amabile et al. 2005).

Education for Sustainability and Awareness Can Be Infused in These Areas

1. Economic growth: To build a sustainable economy that is expanding in the proper direction.
2. Protecting the environment: Another objective is focused on how humans may contribute to safeguarding and improving the natural environment by decreasing waste and pollution, as well as working to lower the global carbon footprint.
3. Social inclusion: This goal focuses on giving future generation's access to housing and supporting the development of robust, healthy, and thriving international communities. Another view, known as "entrepreneurialism" (Cox and Ziv 2005), places a high value on the ability of people to innovate. Anthropocentrism is its defining characteristic, and it aims to reconcile and integrate social and ecological objectives while keeping a clear focus on human needs. It frequently combines economism with technological optimism.

Sustainability education was developed in response to the UN International Environmental Education Program (1975–1995), which had outlined a vision and sparked environmental awareness education. Every person has the ability to develop the knowledge, abilities, attitudes, and values necessary to create a sustainable future through sustainability education. By challenging conventional ways of perceiving and interacting with the world, education for sustainability encourages individuals and groups to reflect on their own experiences and worldviews. Ecological, social, and economic systems that uphold regional and global equity and justice across generations and into the

future are also included in the definition of sustainability for education.

Education Assessment Through Awareness

Teaching the principles of sustainability is a lot like teaching the reasoning behind an abstract concept or learning them by heart. When education assessment is used in real and useful ways, students are given the knowledge, skills, perspectives, and attitudes they need to live sustainably in their communities. An educational initiative called "awareness through education" promotes tolerating people who may appear, learn, or act in ways that are dissimilar from our own and views incapacity (physical, intellectual, and medical) as a normal aspect of the human experience. Sustainability education is recognized as a crucial driver of sustainable growth and a vital tool of high academic standards. This vision and the significance of a suitable educational response are clearly reflected in the 2030 Agenda for Sustainable Development, which the United Nations adopted in 2015. The fourth Sustainable Development Goal on education, on quality education, focuses especially on sustainability education and related strategies (UNESCO 2017). The goal of education evaluation via awareness is to lessen the inherent fear and awkwardness that most students experience when they encounter someone who is different. Through educational tools, self-evaluation raises pupils' self-awareness and involves them in metacognitive activities (Basnet 2011).

Types of Sustainability Education

All academic topics are included in sustainability education, which goes far beyond the curriculum. It equips pupils with practical skills that they may utilize to better the world. It gives today's students the independence they will need in the future. The four basic categories of sustainability education are environmental, human, social, and economic.

Human sustainability: Maintaining human capital is essential to human sustainability. Instead

of being shared by individuals or countries, human resources is a natural monopoly of the individual. Human capital includes people's physical and mental well-being as well as their education, leadership, and service access. Individual investments in their education, health, and nutrition are now recognized as a necessary component of economic growth. Given that the average lifespan of a person is relatively brief and limited, human sustainability requires ongoing upkeep through expenditures made throughout a person's lifetime. The beginning of human sustainability is facilitated by encouraging maternal health and nutrition, safe childbirth, and newborn and early childhood care. To fully achieve some of the potential that each person possesses, human sustainability requires an investment of two to three decades in education and apprenticeship. The expenses of preventative and curative healthcare, adult education, and skill development could be on par with or higher than formal schooling. Human capital needs to be maintained and has a solid structure by controlled population census.

Social sustainability: In order to retain social capital, society must be sustainable. Resources and services that form the foundation of society are referred to as social capital. Community cohesion for reciprocity, mutual benefit, human connection, intolerance, compassion, forbearance, love, and generally acknowledged norms of integrity, discipline, and ethics are components of social sustainability. Social sustainability is promoted through shared norms, regulations, and knowledge (including libraries, movies, and diskettes). The component of social capital that receives the least attention from rigorous measurement but is nonetheless vital to social sustainability is shared values. Given the high rates of violence and mistrust, social capital is undercapitalized. Cultural values, equal opportunities, and connections among people from different religious and cultural backgrounds are all necessary for the maintenance and replenishment of social capital. The most serious barriers to sustainability can be social disintegration and violence (Goodland 2002). The social pillar, which includes free education, housing, work, and access to social services, should be maintained

in order to prevent this at all costs. It also covers health and senior care. It also covers the elimination of poverty, job security, a balanced budget, access to education, nondiscrimination against women, the safety of jobs, the elimination of poverty, and the elimination of all forms of gender-based violence (EU 2019). At various levels, including corporate, geographic, social, and interpersonal (political, ethical, and managerial), social conscience has been sharpened while also offering focus points on sustainability development goals and initiatives. Educating women is one educational endeavor that can raise the economic capacity of entire nations. Additionally, according to Lawrence Summer, the chief economist to the World Bank, "Once all the benefits are recognized, investments in the education of girls may well be the highest-return investment available in the developing world" (King and Hill 1993). As a result, some countries have initiatives to actively educate girls in school and are reducing obstacles to their attendance.

Economic sustainability: This entails protecting and preserving capital. Capital, both economic and manufactured, is interchangeable. Natural capital, like undisturbed forests and clean air, has not received much attention in economics in the past. Economics places monetary value on everything and has a difficult time appraising natural capital, intangible, cross-generational, and especially open-access resources like air. In the face of risk and uncertainty, economic policy should consistently apply and err on the side of caution (Goodland 2002). Trade and investment, job growth, the expansion of the private sector, domestic and global trends, and assets all contribute to economic sustainability. Its tools include national and international financing, government collaborations, commerce and employment policies, and tax policy.

Environmental sustainability: This refers to the laws, rules, and other policy frameworks governing issues such as air and water pollution, solid waste management, ecosystem management, biodiversity conservation, and the environmental conservation, wildlife, and endangered and threatened species. Community involvement is acknowledged as essential to the collective

change toward an environmentally responsible society in sustainability education. Environmental sustainability addresses issues such as environmental deterioration, global warming, global climate change, the environment and human rights, as well as biological improvement, mitigated air quality, enhanced watershed management, and better regulation of resource extraction. Instruments used by national, regional, or municipal governments may include financial incentives, market-based tools like tariffs and tax deductions, subsidies, awareness programs, and educational initiatives (EU 2019). Institutions are expected to make sufficient efforts toward sustainable development, particularly in averting the catastrophe of climate change. University buildings could be constructed to the greatest environmental standards, trash could be reduced, institutional footprints could be smaller, and plastics could be banned from campus completely (Times Higher Education 2019). Additionally, universities might eliminate waste, minimize institutional footprints, and prohibit the use of plastics on their campuses while also building to the greatest environmental standards (Times Higher Education 2019). It is crucial to conduct research on both public advocacy efforts and climate change. Learning should incorporate sustainability. Although sustainable development was motivated by social issues and is a necessity for people, it aims to enhance human welfare by safeguarding natural resources. Natural capital is different from economic capital in that it comprises of resources including land, air, water, ecosystem services, and mineral. As a result, a lot of it gets turned into manufactured or economic capital. The environment encompasses the sources of the raw materials needed to meet human requirements and making sure that the capacity of drains for composting human waste is not surpassed in order to avoid harming people. Humankind must learn to exist within the constraints of the biosphere (Goodland 2002).

Globally Responsible Management Education

Management education is primarily about leadership development for social impact. Students

should be prepared to become ethical leaders in the global community. Management programs highlight their societal and global duty for a shared sustainable future even within traditional professions like accounting, finance, public service, and business administration. An increasing number of research (Muff et al. 2013; Werther and Chandler 2014; Williams 2014) is highlighting the opportunities and obligations that management education has for world development and global prosperity. These trends are already evident in a number of managerial and leadership practices used by businesses that support the UN Global Compact's objectives for human rights, labor rights, and anticorruption (Rasche and Kell 2010; Lawrence and Beamish 2013). These trends are already discernible in a number of managerial and leadership practices used by businesses engaged in sustainable development, human rights, labor rights, and the UN Global Compact's anticorruption agenda. However, many global management programs still need to make some adjustments to their strategic priorities and curricula in order to be more relevant to the trends in global responsibility for profits, people, planet, and sustaining partnerships (Fisk 2010; Sosik and Jung 2010; Wankel and Stachowicz-Stanusch 2011). Learning: The Treasure Within, the report written by the Jacques Delors-led Intergovernmental Panel on Education for the Twenty-First Century, was presented to UNESCO. The report urges for the complete goal of reorienting education to achieve sustainability and strongly advises that all reform be performed in the spirit and substance of sustainable development. Therefore, sustainability goals and education have a legitimate position in whatever modifications result from attempts at national or local educational reform. The audience at the international forum in Vienna identified holistic education, stakeholder awareness, engagement, and capacity building as its main objectives. The difficulty, however, was identified as the timely evolution of human civilization toward a profound transformation. The UN has been successful in integrating the social pillar alongside the economic and environmental aspects. Additionally, it has gained political support on a worldwide scale and

influenced a number of players, including all tiers of government, nongovernmental organizations (NGOs), academic and research institutions, and the general people. Therefore, the worldwide critique will be applied to enhance sustainability education.

Management Education in Theory

It acts as a justification for decisions to be made. An explicit understanding of the theoretical background supporting practice in educational establishments improves managerial activity. Academic scholars have classified models and theories of educational management. According to Cuthbert (1984), there are five categories of educational management theories: analytical-rational, pragmatic-rational, political, phenomenological, and interactionist models. In their quest to comprehend and manage educational institutions, students of educational administration who turn to systems studies for guidance will not find a single, universal theory but rather a variety of theoretical approaches, each jealously guarded by a specific epistemic community (Ribbins 1985). One of the 17 UN Sustainable Development Goals is to provide access to high-quality education. In order to identify the most crucial ESD teaching points, it is first necessary to examine the evolution of sustainable development. Sustainability for education competences (UNECE 2012) present essential characteristics of sustainability education will aid the management education theory with holistic approach, envisioning change, and achieving transformation.

Principled Challenges to Practical Opportunities

A key component of influencing the future is responsible management education, which entails translating theoretical issues into real-world opportunities. The fundamentals of management education are giving students the skills they need to become future producers of creating wealth for

industry and society as well as to contribute to a diverse and viable global economy. The values of international efforts like the United Nations Global Compact, which promote global social obligations, should also be embedded into academic pursuits and curriculum. Establishing educational structures, resources, procedures, and situations that promote successful leadership experiences; doing empirical and theoretical research that enhances knowledge of the dynamics, contributions, and effects of businesses in the production of long-term social, environmental, and economic value; interaction with business company managers to deepen understanding of their difficulties upholding social and environmental obligations and to mutually develop successful solutions to these difficulties; and facilitating and encouraging discussion and debate on important topics relating to sustainability and global social responsibility with interested groups and stakeholders, including education, business, government, consumers, the media, and civil society organizations are all very important for illustrating the tenets of education reform (Tavanti and Wilp 2015).

Culturally Responsive Teaching

By assisting the teacher in comprehending the cultural nuances that may lead to a relationship between the teacher and the student breaking down, culturally responsive teaching (CRT) seeks to close the achievement gap between the two parties. In accordance with sustainability developmental goal 4, a quality education must be comprehensive, inclusive, and encourage learning opportunities for all. It includes entrepreneurship, sustainability education, technical, vocational, and tertiary skills, as well as competence from early childhood education to secondary education (UNESCO 2019). Quality education, according to Ng's (2015) research, "includes holistic development", prepares learners with the skills and abilities for the future, instills students with the correct values, and instills students with a good learning disposition. This is provided by a good instructor, supported

by excellent teaching and learning procedures and holistic learning environment. Universities influence many of the world's future leaders significantly. Therefore, managing, reporting, and building strategy on sustainable development challenges have a big impact (Adams 2018). Change may be prompted by the way students are taught. Teachers who participate in CRT must apply critical intercultural awareness abilities to assess their own values, culture, attitudes, and perceptions with objectivity. This thought gives teachers a better understanding of the history and lifestyles of other cultures. Culturally responsive teaching also entails developing learning environments where students are treated with respect and confidence (Scheurich 1998). Additionally, they offer standards-based instructional methodologies and curriculum through the utilization of demanding, captivating activities that take place in the context of students' cultural and language contexts (Hilberg et al. 2000). Through the integration of their students' cultural and linguistic backgrounds with difficult learning situations requiring higher order thinking and critical inquiry, CRT techniques give teachers the abilities to educate students how to become critical thinkers. Researchers demonstrated to teachers how to incorporate their teaching with students' home experiences in Funds of Knowledge, a well-researched critical thinking mediation (González et al. 2013).

Sustainability Resolution Relating to All Bio-Sectors, E-Sectors, and Allied

According to the Sustainable Development Goals (SDGs) of the United Nations (2015–2030), which are stated by the Aichi-Nagoya Declaration on Education for Sustainable Development (2014), education must address biodiversity, climate change, production, sustainable consumption, and the urgency of the civilizational crisis in the country. It involves safeguarding ecosystems and the elements that make them up from unwelcome changes (Clive et al. 2019). Its goals are to preserve natural resources and the current natural environment, as well as to repair damaged

and reverse trends where feasible. Additionally, there is an urgent need to acknowledge the worth and relevance of traditional knowledge and indigenous insight in all contexts in geographic, socio-cultural, and educational as well as its applicability in environment.

Summary

Sustainability education and awareness depends on people participation towards educational growth. Successful implement must cut across governments and school districts in order to develop strategies, as sustainability and education remain two of the most important topics in human history. The likelihood of effective implementation and curriculum reorientation to attain sustainability will be increased by thoughtful consideration and planning around such challenges as well as issues unique to each location. This approach should cut across all nations and not sectionalized. In principle, increase in sustainability education and awareness level increases the people's good behavioral conduct on environmental, social, and economic sustainability. Governments, institution, private sectors, industries, and businesses should support education for sustainability for a better future and generation.

► Inclusive Leadership

Sustainability in Curricula (SE)

Daniela Lud
Faculty of Communication and Environment,
Rhine-Waal University of Applied Sciences,
Kamp-Lintfort, Germany

Synonyms

Education for sustainable development in curricula; Education for sustainability in curricula

Definition

Sustainability Education (SE) seeks to enable students and graduates to gain and generate knowledge about sustainability, and reflect critically on behavior and decisions for sustainable development in a way that they can contribute to a sustainable future. Instead of the term SE, some authors (e.g., Wamsler 2020) use the term Education for Sustainability (EfS) or Education for Sustainable Development (ESD) (see Weiss and Barth (2019)). The terms sustainability and sustainable development are used interchangeably in this context (Disterheft et al. 2013). Sustainability in Curricula (or EfS/ESD in Curricula) refers to the institutional or academic process of developing curricula or implementing sustainability in curricula in higher education (Barth 2015; Weiss and Barth 2019). Developing and implementing ESD in curricula means to integrate topics of sustainable development like climate change, poverty reduction, biodiversity, and sustainable consumption in teaching through new approaches to all aspects of education (Wiek et al. 2011). These aspects include content of curricula, learning objectives, pedagogies, and assessment of

students' achievements. Structural changes of Sustainability Curricula generated in the process need to reflect that sustainability is a crosscutting issue involving several disciplines (Weiss and Barth 2019).

Introduction

Integration of Sustainability or Education for Sustainable Development (ESD) in Curricula receives increasing scientific interest since the late 1990s (Weiss and Barth 2019). One reason for the recent growth of this area of research is that ESD asks for new, innovative approaches to the development of curricula. This is due to the interdisciplinary nature of sustainability and the systemic implications of the topic. Education for sustainable development originated from environmental education, a concept, which emerged in the 1970s (Barth and Rieckmann 2016; Gamage and de Silva 2022). In environmental education, the focus is to provide information about the environment, to give the opportunity to experience the environment (e.g., during field work), and to foster the development of a personal relationship with nature (Cotton and Winter 2010). Today, environmental education is considered part of ESD (Garcia et al. 2017).

The Brundtland report "Our common future" (WCED 1987) was published by the United Nations to give a strong impulse for sustainable development. With its key topics of intergenerational equity and global partnership, this report represents a milestone in the social and scientific discourse on sustainability. Additional momentum for ESD in institutes of higher education came from a number of international conferences, starting in the 1990s (UNESCO 2018): The United Nations conference on Environment and Development in Rio in 1992 with the Agenda 21 action program introduced ESD (Gamage and de Silva 2022). Ten years later, the 2002 World Summit on Sustainable Development in Johannesburg announced the decade for ESD 2005–2014. The 2012 United Nations Conference on Sustainable Development in Rio showed that global environmental and socioeconomic issues

continued to be challenging. In 2014, the Global Action Program on ESD followed the decade for ESD. Shortly after that, the 2015 Paris Agreement was adopted providing a global framework to try to reduce global warming to well below 2 °C. At the same time, the Sustainable Development Goals (SDGs) were released, which represent a universal call to take steps to end poverty and protect the planet. ESD is crucial to achieve sustainable development and can be regarded as a process of learning. ESD is therefore linked to several SDGs. Most prominently, ESD is part of SDG 4 on quality education (United Nations 2015). More specifically, target 4.7 states “By 2030, ensure that all learners acquire the knowledge and skills needed to promote sustainable development, including, among others, through education for sustainable development” (United Nations 2015, p. 17).

Institutions of higher education have a special role in education for sustainable development, as they teach the change agents of the future (Fadeeva et al. 2014; Salovaara and Soini 2021). ESD aims at increasing awareness for sustainable development as well as developing competencies, promoting sustainable and responsible actions (Rieckmann 2012). Through education, the aim is to enable learners with knowledge, skills, attitudes and competencies to engage and collaborate toward social, environmental, and economic sustainability (Gamage and de Silva 2022) and thereby attain societal transformation. As outlined by Garcia et al. (2017), a development balancing the three dimensions of sustainability asks for an integral and interdisciplinary approach in teaching and learning. Therefore, institutions of higher education have started to integrate sustainability into curricula (Barth and Rieckmann 2016).

Sustainability at Institutions of Higher Education

According to Schneider et al. (2018), there is a special responsibility of institutions of higher education for Sustainability Education. One reason is that these institutions not only are multipliers, but they also educate change agents of the future

(Salovaara and Soini 2021). Besides good governance (Žalėnienė and Pereira 2021), institutions have three fields of activities: teaching, research and community outreach (Fia et al. 2022; Leal Filho and Dahms 2018). In all fields, institutions of higher education can integrate sustainability.

Sustainability in Curricula can be addressed on three levels (Fia et al. 2022): on a macro-level (e.g., activities referring to all university or campus such as strategic and policy issues), on a meso-level (for instance, referring to activities of a faculty or a study program). Activities or content regarding individual courses or individual workshops are regarded as micro-level activities (Cotton and Winter 2010). Activities on all three levels are interrelated. Implementing sustainability via a strategic whole institution approach achieves higher impact compared to fragmented activities on individual levels. This is because a strategic approach leads to synergies between activities on macro-, meso-, and micro-level and helps to overcome common barriers to implementation of Sustainability in Curricula (Weiss et al. 2021; Zepeda Quintana et al. 2022) (Fig. 1).

Curricular Versus Noncurricular Sustainability Education

Sustainability education can take place in formal and less formal settings (OECD 2007) and in curricular or noncurricular format. Formal learning refers to situations of an organized learning process leading to qualifications like degrees and diplomas. Nonformal educational settings include organized forms of education, where usually no qualification is obtained like community learning or learning organized in volunteer activities. Informal learning describes educational situations which are not organized and where learning takes place unintentionally (OECD 2007).

Sustainability Education in institutions of higher education can be facilitated in different modes (Pallant et al. 2020): curricular education, cocurricular education, which are both formal forms of education and extra-curricular education, which is less formal as no qualification is obtained usually. Curricular education has the advantage

Sustainability in Curricula (SE),

Fig. 1 Macro-, meso-, and micro-level of the implementation of Sustainability Education at institutions of higher education (own work based on concepts of different levels of implementation in Fia et al. 2022; Kleiman 2010; Weiss and Barth 2019). Strategic whole-institution approaches create synergies and make the implementation more efficient

that students get credit points and receive support of teaching staff (Gamage and de Silva 2022).

At institutions of higher education, Sustainability Education not only takes place via the formal curriculum, but also via the so-called hidden curriculum (Chambers et al. 2016; Cotton and Winter 2010). This term is used to refer to unintentional learning opportunities through campus culture and values expressed on campus, e.g., if the university is a Fairtrade university, decisions are taken in democratic ways or if waste is separated. This provides students with implicit learning opportunities, which are complementary to learning opportunities of the formal curriculum.

more sustainability in Curricula. This holds especially for learners. Boarin et al. (2020) state that sustainability is perceived as a critical element of curricula by learners at different levels of higher education. Students prefer having more sustainability classes as integral part of curriculum (Grund and Brock 2020; Wang et al. 2022). According to Garcia et al. (2017), ESD needs new and participatory educational methods, which enable students to gain knowledge and activate them to change behavior. This is in line with the observation that processes of curriculum innovation can be initiated and led by students (Weiss and Barth 2019).

Sustainability in Curricula

There is a growing body of literature on ESD at institutions of higher education. The most important topic in this field of research is the development of curricula (Barth and Rieckmann 2016). To date, there is no consensus regarding the content of a sustainability curriculum (Gamage and de Silva 2022; O'Byrne et al. 2014). Therefore, sustainability contents in curricula are described via characteristics rather than via topics (Disterheft et al. 2013): ESD is supposed to be inter- or transdisciplinary, takes on an integrated approach, and aims at transformative action. In general, teachers and learners are in favor of

Competencies and Methods for Sustainability in Curricula

The idea of ESD is to change societies through learning and through facilitating the acquisition of competencies (Fadeeva et al. 2014). This means that graduates are provided with a literacy in sustainability. This results in graduates with the ability to critically reflect on economic growth, consumption patterns, digitalization and globalization (Fadeeva et al. 2014). To achieve this, competencies were defined and described by several authors. According to Wiek et al. (2011), a competency is a "functionally linked complex of knowledge, skills, and attitudes that enable

successful task performance and problem solving.” One of the influential contributions regarding competencies for Sustainability Education is De Haan (2006), who developed the concept of *Gestaltungskompetenz* (shaping competency). Shaping competency refers to the competency of acting and problem-solving based on skills, knowledge, and competencies for behavior change to reach sustainable development. Shaping competency comprises several key competencies, among others competency in anticipatory thinking; competency in interdisciplinary work as well as awareness of global relations and cooperation. Further work was done by Brundiers et al. (2021), Cebrián et al. (2020), Lozano et al. (2017), and Wiek et al. (2016). In a review of competencies mentioned in descriptions of 45 master programs related to sustainability science, Salovaara et al. (2020) found that the competency of strategic thinking, normative competencies, and the competency of systems thinking were the most frequently mentioned ones.

Based on competencies, concepts for pedagogies and methods to teach sustainability were developed. Evans (2019) derived five competencies and five pedagogies to teach these. Generally, it was shown that integrated (interdisciplinary and transdisciplinary), participative, and applied methods work best. Especially problem- and project-based methods combine very well with most sustainability competences. Both methods share some common characteristics such as focus on applied, real-life topics. Problem-based methods facilitate deeper understanding of theory, thus learning is more student-centered, whereas project-based methods yield more case-specific insights, offer opportunities to learn project management, and often result in practical products related to the project (Brundiers and Wiek 2013). Research shows that problem-based and project-based methodologies are useful and effective educational settings for the implementation of ESD in teaching (Álvarez et al. 2021; Brundiers and Wiek 2013). Other frequently used methods are service learning, also known as community-based learning. Here, students get involved as volunteers in social groups or projects and typically receive credit points for their studies. Additionally,

methods like cross-disciplinary workshops, case studies, and simulation games are used (Cebrián et al. 2020). It is important to note that ESD and curricular innovation also require training, competencies and support of educators (Anastasiadis et al. 2021; Fadeeva et al. 2014). Professional development of teachers’ competencies works best if integration of sustainability is approached in a strategic whole-institution effort (Fadeeva et al. 2014).

Challenges of Implementing Sustainability in Curricula

One of the key obstacles of curricular innovation is the discipline-based structure of many institutions of higher education, which hampers interdisciplinary approaches required for ESD (Disterheft et al. 2013; Harré et al. 2020; Weiss et al. 2021). If institutions apply reductionist approaches limited to one of the dimensions of sustainability only, the potential of ESD cannot be reached (Disterheft et al. 2013). The introduction of institution-wide sustainability learning outcomes can help to overcome disciplinary boundaries (Levesque and Wake 2021). Weiss et al. (2021) describe different degrees to which sustainability is implemented into curricula at institutions of higher education. Weaker forms are characterized by a level of implementation with Sustainability Education as add-on to the curriculum rather than stronger forms with built-in Sustainability Education or completely redesigned curricula. Further barriers include lack of strategy or vision and organizational issues such as lack of resources and organizational structure (Weiss et al. 2021) and crowded curricula (Verhulst and Lambrechts 2015). Greenwashing and commercialization of education may be challenging for the introduction of sustainability curricula in institutions of higher education (Disterheft et al. 2013), especially if the implementation is weak. Good coordination, an institution-wide strategy and interdisciplinary collaboration are enabling factors for the implementation of Sustainability in Curricula. Strong leadership and simultaneous implementation of sustainability in all fields of

activities of institutions of higher education is beneficial (Weiss et al. 2021). Other challenges include human factors such as reluctance to change or lack of awareness (Verhulst and Lambrechts 2015). This means that a good integration of top-down approaches and bottom-up processes is important for successful implementation of Sustainability in Curricula (Verhulst and Lambrechts 2015).

Summary

The United Nations decade for ESD (2005–2014) as well as the SDGs inspired institutions of higher education to integrate Sustainability in Curricula. This requires activities on a strategic, whole-institution level, but also on the level of faculties, study programs, and individual courses. Important barriers to implementation are disciplinary boundaries and a lack of strategy and vision. Key enabling factors are strong leadership, interdisciplinary competency of staff and other actors as well as integration of top-down and bottom-up processes.

Sustainability in Economy of Communion Enterprises

Maria-Gabriella Baldarelli
Department of Management, University of
Bologna, Rimini, Italy

Synonyms

Civil economy; Sharing economy; Sharing organizations; Social and civil firms

Definition

Sustainability in Economy of Communion enterprises (EoC) is the economic expression of a charisma that is implemented in the economic field. It considers the company as part of a wider life that is based on values and on the view of world fraternity among people and organizations in order to solve poverty issues.

The analysis develops in the understanding of the evolution starting from frail sustainability to robust sustainability in EoC companies. It is necessary to proceed by successive approximations, so we propose to concentrate the consideration on some pillars and gears, which we found particularly implemented in the EoC and which are assuming considerable relevance from a theoretical point of view as well.

Economy of Communion is the economic expression of a charisma (Bruni and Sena 2013; Baldarelli 2013), but it is also the source of a new culture that develops only if it is shared and if there is an attitude of openness toward the discovery of new ways of company management and of the existence itself thought out and realized while acting together. The implicit potential in the EoC may be developed in comparison and in “communion.” That is, in the ability of questioning oneself in order to reach new solutions for new problems within a logic that considers “eudaimonic happiness” as the preeminent aspect of thinking and acting together.

EoC Pillars in the Passage from Frail Sustainability to Robust Sustainability

The pillars, that we will deal with, are dialogue, trust, and reciprocity.

Dialogue is intended as accurate dialogue, which creates trust within itself, and it is the result of care and of a positive and truthful relationship. Dialogue which is not created without listening to and sharing with the other players with whom we are speaking, so we are not talking of a merely contractual relationship, rather we try to go beyond and develop a relationship which involves economics, social, and environmental aspects that

are based on values (Lubich 2001; Argiolas 2017).

The meaning of dialogue is better understood if we refer to the reputation of interactive relationships, till so long as a real evolutionary classification underlining the various constructive implications, even from the economic interpretation, these bring (Ruisi 2011).

Concerning this, we must not forget an important trend, represented by the gradual diminishing of interpersonal goods, which has directed to the formation of the novel “poor,” who have various positional things, but have few accurate relations, and, for this reason, they are unfortunate (Bruni and Porta 2006). It follows that the existence of relational “new poverties” tends to deteriorate and flatten the overall economic system and, consequently, the businesses themselves too. The relationship is necessary to go far outside the contract and embrace gratuity, at minimum in one of the two parties (Baldarelli et al. 2015; Baldarelli and Del Baldo 2017). The second aspect, which we will analyze, regards trust (Pelligra 2007), which is generated by way of the typology of relations just outlined and, particularly, whenever the parties place themselves on the same plane without the utilitarian purpose of one abusing his/her power over the other.

Second, in order to generate trust, you need to be able to put yourself in the position of the other party and to fully understand their problems.

Reciprocity, according to the model adopted, points out various relational modes, which we will explain. The same author subdivides reciprocity into three categories, viz., “cautious,” “philia” (brotherly love), and “courageous.” The first is so defined: In order to make cooperation possible, it is necessary that there are players to imitate who are pioneers in this activity (Bruni 2006; Bruni et al. 2008); the second kind of reciprocity-philia works in cooperation if there are the following conditions: equivalence, namely the adequacy of the reaction, equality, freedom, nontransitivity and conditionality, or rather an element in common; “courageous” reciprocity, on the other hand, always works in cooperation (Bruni et al. 2008). Such an interaction form is healthily stated by the reciprocity relation wherein open-handed and

getting is experienced. This form of reciprocity consists in the incidence of an inherent reward the player gains from the act itself, both previously and regardless of the consequence.

To take this path, we underline also the importance of the good life by seeking truth, goodness, and beauty within the company decision-making process.

The pillars highlighted go into the undercurrents of commercial activities and, therefore, of businesses generating originality and sensibility toward destitution and poverty, and they act as motors of the passage from weak sustainability to strong sustainability.

EoC Tools in the Way from Frail Sustainability to Robust Sustainability

In the EoC business, a part of functioning time is expended on constant building up and lacing relations. Communion must always be searched for. For this reason, it is important to equip oneself with tools which may favor facilitating processes in order to boost it or rebuild it (Argiolas 2017).

Signing up to a Pact on the mission requires clearly – although still dynamically – significant it, representing which elementary principles the firm will have to magnet motivation from the relations that it will launch with the stakeholders, whether they be inner or outside ones, close or distant.

The second tool is sharing which consists of giving one’s own experiences, but especially, how they have impacted the ways of seeing problematic issues and finding solutions within themselves, sharing that which one is with the others, with all correlated characteristics and skills, successes or failings, worries or hopes.

The third is sharing experiences. Some knowledge, experiences, risk “dying out” in whoever has them if they are not shared. A way to let your professional competence of which you knowingly are aware be known, and a way of acquiring yet others.

The fourth tool is testing. It includes a pathway that permits, both the worker and internal/external

agent, to improve his/her labor relation, in qualitative terms (Baldarelli et al. 2015). It may be brought about through periodic consultations in small clusters harmonized by a moderator who has the task of ensuring that whatever is said goes for the real benefit of the single persons and of the company: It is a chance to together remove what the stumbling block is, or decisively drive toward that which favors original “life,” original “ideas” in the business as well, since one does not stop at correcting a mistake, rather goes on to reciprocal growth.

In the colloquial interview, which is the final tool we will analyze, both questions relating to the trend of company life, of communion relations among its leaders, but also the position of the individual person with his/her needs of various types are considered, depending on cases and players involved. So that the colloquial interview produces its effects, total listening is necessary, moving our culture, our way of being to welcome the other. The point of gravity shifts from I to “We.”

The originality is in not ever tracking singular choices, rather decisions taken together for the quality of life of the third party who has to bear the consequences of them. All this helps to overcome the limitation of the ego which, trustfully speaking, generates reciprocity.

The tools analyzed develop in the definition of the purposes, in the behaviors of governance, and in the statement of the company. They allow the decision-making procedure to progressively change until it includes those characteristics of strong sustainability, which we are here dealing with.

Summary

These considerations about EoC pillars and tools stand not just for companies; however, the dynamics originating mean revitalization of the market, of the economic system and society which, in this way, becomes, authentic for a rediscovery of values and beauty of putting them into practice.

Finally, in the EoC scheme, we glimpse at an effective support to the combination that changes old-style knowledge, which especially deals with both scholars within the same branch of learning, and an interdisciplinary dimension, in “wisdom.”

Sustainability in Tourism Marketing (Sustainable Tourism Marketing)

Nil Sonuç

Faculty of Tourism, İzmir Katip Çelebi University, İzmir, Turkey

“If we leave environmental protection to environmentalists, marketing products to marketers and social equity to activists groups, the system will be separated, and common objectives are hard to achieve. Sustainable marketing has sustainability as its underlying objective. This includes a quality of life instead of standard of living. A sustainable approach provides a macro-holistic view of marketing and integrates economic viability, social equity and environmental responsibilities towards the desire to achieve livable and living communities” (Jamrozy 2007, p. 125).

Introduction and Theoretical Framework

Definition

Sustainability in the framework of the marketing of tourism or sustainable tourism marketing means marketing of tourism products and destinations respecting, protecting, and preserving the environmental and cultural resources and local livelihoods. The tourism marketing paradigm is signaled to shift from economic profit priorities toward sustainability. In this respect, marketing approaches are indicated to evolve from the production, sales, and customer orientation toward marketing alternatives such as societal, causal, green, responsible, and relationship marketing (Jamrozy 2007). The study of Constantinides (2006) can be visited in order to see the evolution of marketing approaches in general beginning from the 1960s till the appearance of e-marketing

and suggestions for the twenty-first-century marketing. The STMM (sustainable tourism marketing model) suggested by Jamrozy (2007) integrates tourism into a larger holistic context and focuses on marketing a quality of life for all stakeholders in the system. It is indicated in this study that “the fundamental shift is to market tourism not as a leisure product but as an experience that enhances quality of life, not just for the individual participants, but for living systems at large; the human and non-human, the guests and the hosts. Such an integrated view perceives tourism as a social psychological activity, where the benefits are not or not only economic profits, but also (ex) changes of ones own belief system, an appreciation and a sense of need for diversity. The tourism system is not limited to demand and supply but a system of synergetic agents. Tourism experiences do not ‘add’ to the quality of life but are part of living system communities” (Jamrozy 2007, p. 126).

Main Issues Related to the Sustainable Tourism Marketing

As sustainable tourism is a multidisciplinary field involving multifaceted actors and businesses, interrelated and interconnected are the marketing conceptualizations for sustainable tourism. It is not easy to decide by the sector how to communicate its sustainability in terms of the practices of the tourism businesses as well as the message attempted to be given to the consumer side. Thus, sustainable marketing of tourism involves a huge array including the tourism products, the tourism businesses, the destinations, and the consumers.

Beginning from the current research areas for tourism marketing and their related subtopics, they are resumed as follows: Consumer behavior (motives, perception, satisfaction); market segmentation, targeting, and positioning (psychographic and behavioral segmentation factors); brand management (destination branding, destination image, destination personality, destination image measures); service performance (service quality, service delivery, service failure); demand

models and pricing (demand prediction models and pricing strategies); strategic marketing and marketing concept (market orientation, relationship marketing, experiential marketing); and e-marketing (transaction, promotion, Web 2.0, user-generated content, social media, and mobile services) (Tsiotsou and Ratten 2010, p. 534).

“Management of demand” is emphasized by Kastenholz (2004) playing a central role in the context of a careful target marketing approach as an important instrument for the sustainable development of a tourist destination. Market segmentation, targeting, and positioning (Tsiotsou and Ratten 2010) according to the new consumer trends such as ageing population, students and their families at foreign countries, and ethnic (Dolnicar and Leisch 2003; Chen and Uysal 2003) and budgetary segmentations (Tsiotsou and Ratten 2010) are suggested as the research areas to be realized. Font and McCabe (2017) emphasize the importance of sustainability in the tourism and marketing conceptualizations, and they question in what ways the importance of sustainability in the future world of tourism can be communicated by the tourism academicians to especially marketing professionals that are practicing in the tourism industry. Dinan and Sargeant (2000) argue that the tools and techniques of “social marketing” may have much to offer tourism organizations seeking a more sustainable approach to their market.

In addition to the mentioned areas to research and development, many new concepts and factors are to be inevitably involved in the seriously planned sustainable tourism marketing programs. That is to say, the ever-evolving technology and multidisciplinary concepts of sustainability drive the global business and management practices including those of the tourism industry to adopt new paths and methods for the adaptation. e-Marketing thus has become a popular pathway for this new era of economy as well as the concepts such as “individualized,” “specialized,” and “tailor-made” production and communication means. Social media and e-word of mouth (eWOM) are explored in the context of IT applications of tourism as a very important aspect of marketing for tourism (Beckendorff et al. 2019; Xiang et al. 2015).

A few of the most important arguments that underscore the potential that tour operators have in promoting sustainable tourism are dealt with by the study of Budeanu (2005). One is looking for a possibility for the mass tourism to become sustainable. Another suggestion is that there is a lack of incentives for the tour operators to support the adoption of more sustainable behaviors on the side of their customers and suppliers. Another argument is the pivotal role of the large tour operators in designing policies and actions to help all tourism stakeholders make positive contributions to ensuring environmental, cultural, and economic sustainability (Budeanu 2005). OTAs, social media, and other channels are used more by Gen Y which are much more active and much more engaged in travel planning (Xiang et al. 2015).

Massi and De Nisco (2018), for example, mention about the e-marketing of the ecotourism handled from both the supply and the demand sides to suggest what is missing on the demand side especially. The study of Sharpley and Pearce (2007) examining the case of the English national parks can also be referred if the sustainable tourism marketing and the related ecological and socioeconomic aspects are required to be revised and understood. The sustainable tourism marketing is mentioned by Eiseman (2018) emphasizing the co-productive process between consumer and producer additionally, by exemplifying certain destinations employing demarketing in order to decrease the quantity of waste and the harm given to the environment because of the touristic activities. If the choice of more sustainable tourism products and practices are encouraged by the suppliers, then the marketing of a more sustainable behavior on the consumer side is mentioned as the economical dimension of the sustainable tourism (Jamroz 2007, p. 124). Issues related to the sustainable destination management in today’s world involve not only the sustainability of the destinations and encouraging more sustainable consumer behaviors; it does not suffice. Demarketing has become a useful tool to facilitate the life at the destination for both sides of the host and the guest and to avoid the negative impacts of tourism and increase sustainability at the destinations.

Consumers of tourism products look for alternative holiday concepts. A growing number of public choose greener products to avoid giving harm to the environment while on holiday. Environmentally sustainable labels have become the key tool to gain competitive advantage for some tourism businesses. “Green sells... postmodern travelers want to believe that their use of tourism facilities and their presence in tourist destinations, will not damage the resources they visit and embrace the promises offered by tourism companies” (Font and Buckley 2001, p. 1). On the contrary, the green products may be avoided by the consumers as these products require higher prices. About the marketing and communication of the sustainable tourism practices of businesses, “greenwashing” and “greenhushing” are two concepts to be mentioned which are placed at the negative and the positive extremes of the interpretations of sustainability (Font et al. 2017; Delmas and Cuerel Burbano 2011). In fact, greenwashing is perceived negatively, and it is mostly made for a brilliant image and perception of sustainability even if the efforts of sustainability practiced by the business are far less or even nonexistent. And it is practised to gain financially more. On the contrary, greenhushing is communication of a less number of practices of sustainability than existing efforts and practices. That(greenhushing) saves the businesses from losing the customers who would on the contrary escape and eliminate their visits. Because in general, the green holidays are perceived costly in the consumer's eye (Font et al. 2017).

It is quite difficult to decide where to stop and how to act while communicating the sustainability in tourism marketing to the clientele. Hanna et al. (2018) examining the consumers' point of view found out that consumers support the messages of the businesses concerned with sustainability placing greater priority upon affordability of consumer experience and opportunities expected at the “sustainable” destination rather than the overt discourses of sustainability which are rejected. Similarly, in an empirical study to discover how the purchase decisions could be better influenced in travel brochures, it was found out that preference is confirmed by consumers generally for emotionally laden communication styles for

sustainable tourism products while they stayed indifferent for the sustainability attributes and standard product features (Wehrli et al. 2017).

To understand sustainable tourism marketing, destination-related conceptualizations carry a great importance. Sustainable tourism development and marketing are mentioned by some as bringing a competitive advantage to a destination (Kiral'ova 2019; Hassan 2000), while it is regarded by some others as the role of governmental function of the host communities to control the negative impacts of tourism (Basu 2017). Opposing to the “traditional concept” and “systemic approach” to the destination, the most recent destination concept is suggested as “smart destination” with the adoption of ICT and adaptation of digitalization which involves “interweaving of digital and real realms, public-private-consumer collaboration, participatory governance, creative and knowledgeable people, value co-creation, personalized services” (Jovicic 2019, p. 280). The impact of technology over the sustainability of tourism and tourism marketing can also be mentioned as an area to be researched. A research shows the usefulness of the virtual reality technology implications in sustainable tourism marketing in such a way to contribute to the choice of visiting intentions of potential visitors by making them experience the destination by a virtual 3D technology (Huang et al. 2016).

Vertical integration, with, for instance, Airbnb also engaged in marketing activities at the destination level, means that a growing share of revenue is channeled toward global corporations, a process in which even very small enterprises are involved. Here, the collaborative economy contradicts various goals linked to reduced inequality (goal 10) (Gössling and Hall 2019).

About the sustainable marketing of cultural heritage tourism, a sustainable heritage tourism marketing model (SHTMM) was suggested by Chhabra (2009) including the local community involvement/benefits, preservation and conservation as the sustainability aims, and the environment analysis, partnerships, and marketing mix components on a holistic model. Similarly, the study of Gilmore et al. (2007) framing the sustainable tourism marketing at a cultural heritage site points out the importance of an ongoing

collaborative, interactive, and hands-on management with relevant expertise to create a strategy of sustainable tourism marketing.

About the environmental behavior formation related to sustainable tourism marketing, the findings of the study of Dolnicar and Leisch (2008) show that selective target marketing represents a feasible complement to current sustainable tourism management techniques which focus on tourists at the destination who may not necessarily be interested in protecting the local environment.

As a summary, sustainable tourism marketing is an evolving area composed of many areas to research, develop, and control continuously including the consumer behavior and psychology, pricing, positioning, communicating, distributing, and promoting by benefiting from the technology and innovations while defining long-term, holistic, multidimensional, cooperative, inclusive, strategic, and adaptive managerial and operational plans and programs which preserve, protect, and respect the three basic pillars of sustainability.

Summary

For a further clarification of the conceptual framework of the “sustainable tourism marketing” or “marketing for the sustainability of tourism” or “sustainability in tourism marketing,” it is inevitable to accept that the discussions (e.g., by Pomeroy et al. 2011) and suggestions (e.g., by Jamroz 2007; Pomeroy et al. 2009) are made and confusions exist in the area. However, there is a need for researching more distinctively about the clarification of the conceptualizations and measurability of this field of marketing. The terms related to sustainability carry always the same meaning; they do not change meaning when they are combining with the marketing of tourism or tourism marketing. The concept of “sustainability” is not and should not be limited and reduced to only the meaning of “time” or “longer period of time” in terms of sustaining the marketing efforts. If done so, the whole “sustainable tourism marketing” conceptions will also be interpreted or understood falsely. Sustainability as usually referred to by Brundtland Report is

defined as an aspect of development that “meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED 1987, p. 43). The corrective action toward the sustainable tourism marketing conceptualizations and applications should be followed by this angle. Lansing and De Vries (2007) argue that a universal recognition and objective evaluation criteria must be defined first for the sustainable tourism practices and then would follow the sustainable tourism marketing which will be ethically more correct.

As summarized by the study of Pomeroy et al. (2009), tourism marketing includes both tangible and intangible product and services mix and people on both sides of the supply and the demand. And additionally, to cover and comprise all these components as well as the sustainability issues which are inevitable to apply in any sector in today’s world, a contemporary marketing mix for sustainable tourism marketing is suggested. Thus, it is indicated to include the 4Ps of the product marketing mix which are “product, place, promotion, and price.” Additionally, the 3Ps of services marketing are “people, process, and physical evidence.” And also the 3Ps for tourism by Morrison (1989, p. 503, 505) are “packaging, programming, and partnership.” Then this tourism marketing mix of 10Ps content is suggested to be intersected with the reflection of three basic pillars of sustainability (social, environmental, economic pillars) to the sustainable tourism marketing mix as 3Ps of sustainable tourism marketing, namely, “populations, planet, and profit” (Pomeroy et al. 2009).

Definition

From a social and environmental perspective, sustainability is a relatively recent concern in people and, therefore, in companies. Currently, investors require corporate actions to manage the consequences of companies' activities on society and the planet. Moreover, when investors select their financial asset portfolios, they consider the risk of such investments, that is, the possible variation in expected return. The relationship between sustainability and risk has been little studied in the literature, both theoretical and empirically. Most of the scarce research found that the most sustainable companies have a more stable market price, especially in the long term.

Similarly, sustainable market indexes are less volatile and more stable in periods of crisis than the other indexes. Interest in linking sustainability and market risk is recent, and researchers have not yet shown sufficient interest, despite the important practical implications. Without a doubt, we can

say that portfolio managers are ahead of scientific research. In any case, there are theoretical reasons and empirical data to affirm that better management of business sustainability leads to a reduction in market risk, whether this is considered as the variation of cash flows or as the volatility of share prices. Moreover, in the latter case, at an individual company level or collectively, as a market index.

Introduction

Sustainability is a concern in companies in the last decades. Economic development implies negative consequences for the environment and causes social changes that are not always desirable. In this sense, and because of the scandals produced by large corporations regarding polluting activities, the exploitation of workers, etc., a code of ethical conduct was imposed to oblige those companies that want to stay in the market to apply corporate social responsibility (CSR) policies. Companies have to be accountable for their actions. In this sense, the United Nations established the Agenda 2030, a set of sustainable development goals to care for the planet and people, including fighting against poverty, clean water and energy, decent work, gender equality, etc. All of this implies cost to companies. However, do the benefit they get in return compensates for such efforts?

CSR has been widely studied in the literature. An extensive array of research has focused on measuring its three components: environmental, social, and governance (ESG), to determine the final ESG score. Another line of work has established, in general, a positive relationship between financial performance, which is measure as accounting profitability or market valuation, and CSR. There are even comprehensive previous theoretical and empirical analyses about the composition of the board of directors and CSR's extent, focusing on gender diversity (Valls Martínez et al. 2019, 2020). However, so far, little attention has been paid to the relationship between sustainability and market risk.

Today, portfolio managers and individual investors consider ESG-score a critical variable in financial asset selection. Every rational investment decision must consider two basic parameters: profitability and risk. Currently, the concept of profitability includes not only financial performance but also social and environmental performance, and even psychic performance (feel good about their own decisions). The risk is the possibility of not obtaining the expected returns. Therefore, are sustainable companies more or less risky than those that do not apply sustainability measures?

There is little empirical research on this issue, but most find that those market indices that comprise sustainable businesses are more stable over time. Similarly, those companies with better ESG-scores have a less volatile share price.

Relationship Between Sustainability Management and Market Risk

In the middle of the twentieth century, Bowen's book *Social Responsibilities of the Businessman* (Bowen 1953) was the beginning of CSR research, which was linked to its founder's philosophy and character. A few years later, that perspective evolved and moved from a personalist vision to consider the company's commitment to society. In this way, the company's objective is no longer to maximize shareholders' profit. Now it is also essential to take into consideration stakeholders' interests. However, in the 1990s, with the advent of international financial, social, and environmental scandals, a whole set of ethical codes of conduct emerged to control these risks, involving companies in achieving a sustainable model, in this sense, for example, the *Green Book* of the European Union.

Consequently, we can say that there existed a CSR before the current regulatory phase. Indeed, the real origin of CSR has its roots in religious tradition. The *Monte de Pietà*, financial institutions emerged in Italy during Renaissance under Catholic Church auspices, prohibited usury and provided loans for the most disadvantaged sectors

Sustainability Management and Market Risk, Fig. 1
Company stock risk

of the population. Similarly, the Islamic Sharia forbids the *riba* (abusive gains made in trade) (Martín Cervantes and Valls Martínez 2021).

Market risk can be understood in different ways. Some studies identify market risk with the variations in the company's products price. In this sense, those companies committed to sustainability achieve stable market prices, thus reducing the volatility of the company's cash flows. For example, the small ecological production of coffee in Brazil shrinks the volatility of market prices, thus improving the living conditions of farmers, avoiding emigration to large cities. In this way, developing countries' economy is improved (Pronti and Coccia 2020).

On the other hand, it has been proven that one of the problems in ensuring the supply of food at stable prices is the environmental degradation of land, water, and energy resources. Therefore, it is necessary to carry out actions that guarantee environmental sustainability and resource efficiency (Becker et al. 2014). In short, considering the link between CSR and cash flows, in volatile economic environments, and especially in times of crisis, companies that want to have better financial results increasingly resort to implementing and disclosing sustainable activities (Erokhin et al. 2019).

However, when considering the investment in financial assets, mainly in company shares, either individually or through collective investment institutions (such as mutual funds or pension plans), market risk refers to stock prices volatility (see Fig. 1).

The total *company stock risk* is the fluctuation of the stock market's share price. This risk is the sum of two components: the systematic risk and

Sustainability Management and Market Risk, Table 1 Stock volatility

β	Strategy	Volatility	Market risk
$\beta > 1$	Aggressive stocks	High volatility	Above-market risk stocks
$\beta = 1$	Neutral stocks	Normal volatility	Equal-market risk stocks
$\beta < 1$	Defensive stocks	Low volatility	Below-market risk stocks

$\beta < 0$ is not usual and implies that the stock prices move opposite the market

the idiosyncratic risk. The *systematic risk* depends on the market in which the financial asset is traded and encompasses economic, monetary, political, and social factors affecting the particular market. *Company idiosyncratic risk* includes all the aspects of a company or industry. In other words, it arises from the uncertainty that surrounds a company due to the development of its business, whether due to the company's circumstances or those of the sector to which it belongs.

Systematic risk affects all market assets to a greater or lesser extent. It is determined by a parameter called *beta* or *volatility coefficient*, β , and whose value reflects the volatility of the share price compared to the average volatility of the market in which the security is traded (see Table 1).

According to Table 1, if an investor is risk-averse, will prefer defensive stocks, that is, lower beta. In this way, when the market rises the profit obtained will be less but, likewise, when the market falls, the losses will also be reduced. In other words, the risk assumed with the investment will be lower if the stock remains

more stable over time, which requires shorter betas.

Environmental performance reduces both systematic risk and beta (Salama et al. 2011) as well as idiosyncratic risk (Utz 2018). As it is known, CSR integrates environmental, social, and corporate governance (ESG) measures. Studies have found a negative relationship between CSR and stock price volatility, in such a way that those companies that apply CSR policies to a greater extent show higher stability in the stock market price of their shares (Adascalitei 2015; Benlemlih et al. 2018; Xu and Liu 2018). However, this relationship varies according to CSR's dimension considered, being especially strong in the case of environmental responsibility (Nguyen and Nguyen 2015). News that negatively affects the company's reputation positively influences its volatility. CSR's effects on risk are felt more in the long term than in the short time (Bosch-Badia et al. 2018), and, therefore, companies need to protect their image in society.

Market indices include companies qualified as socially and environmentally responsible. Finally, when comparing sustainable market indices, such as Dow Jones Sustainability, with other market indices, it can be seen that ESG indices offer better returns and are less volatile. Therefore, socially responsible investment is suitable for sustainable companies, investors, and society (Lupu et al. 2016).

The influence of sustainability on risk reduction is mainly based on *Stakeholder Theory* (Freeman 1984). Directors must consider all stakeholders' interests (customers, suppliers, investors, public administration, and people in general), not just shareholders, to protect the company from economic and reputational losses. When companies develop and effectively disclose CSR policies, they create a culture of safety toward their stakeholders, who, in the event of a crisis caused by a social (such as worker exploitation) or environmental (such as exceptional pollution) scandal, impose less severe penalties. Consequently, CSR makes companies more resilient and better able to withstand such harmful incidents than their competitors. In this way,

CSR becomes a kind of shield that protects companies from negative assessments of specific actions, giving them a margin of action that would otherwise not be allowed (Nguyen and Nguyen 2015).

In short, when a contingency occurs, companies with marked CSR practices tend to suffer the consequences later and with less intensity than those that do not implement such policies. For example, if the company takes measures to control the waste it discharges, it is less likely to produce accidental contamination. Therefore, its reputation will be less affected, and fines related to environmental damage or a reduction in sales due to the loss of customer loyalty will not reduce economic returns. Besides, workers will feel more involved in repairing the damage, willing to work longer hours and seek outside support, for example, by asking for help from public authorities or involving the general public in helping the company by purchasing its products.

Therefore, CSR measures reduce the probability of adverse incidents and, if they occur, mitigate the negative effects. Customers, workers, and people are safer. For instance, if the company invests in the products' safety and conducts severe good working tests, the customer's risk of an accident will be minimal. Similarly, properly occupational health and safety plan investment lead to fewer workers suffering casualties. Analogously, sustainability measures (reducing polluting waste, renewable energies, water savings, etc.), although costly, reduce the risk of environmental incidents, which have disastrous consequences for the planet and the company's profitability and reputation.

On the contrary, if companies disregard stakeholders' interests, they will have high costs in the future, such as those arising from claims for damages to workers, the population or the environment, stricter regulations, negative image, and loss of credibility with customers, etc.

It is not enough for companies to implement adequate social and environmental sustainability policies; they must also transmit these practices to their stakeholders. Namely, they must make an efficient disclosure. Higher disclosure means

greater corporate transparency, facilitating access to credit by reducing capital restrictions. Therefore, the company's idiosyncratic risk will be lower. According to the *resource dependence theory*, this idea established that companies need to control access to resources for their survival. Since the resources are in the stakeholders' hands, it is essential to gain their trust to ensure access to the resources required at all times.

In addition, reliable disclosure contributes to enhancing the company's reputation (fair remuneration of the workforce, adequate working conditions, energy efficiency policies, pollution control, etc.), strengthening the confidence of the capital markets, and, consequently, reducing systematic risk as well as the volatility of cash flows (Benlemlih et al. 2018). In this line, *legitimacy theory* states that shareholders reject companies whose activities are not desirable or appropriate according to a set of values and beliefs considered to be socially correct. This fact would lead to the withdrawal of invested funds, resulting in increased share prices volatility (Tasnia et al. 2020).

To summarize, risk management theory considers total company stock risk to be the degree to which a company's stock price varies over time. This total risk can be dissociated into two different risks: systematic and idiosyncratic. The company's systematic risk is determined by the particular market to which the company belongs, that is, by its specific environment. On the other hand, company idiosyncratic risk derives from its peculiar characteristics. The company's sustainability policies reduce both the total risk of its two components, that is, the systematic risk and the idiosyncratic risk (Lueg et al. 2019).

Conclusions

Sustainability scores are a fundamental variable in financial investment so that investors scarcely demand unsustainable companies. Moreover, every investor must consider the risk involved in the selected financial asset. In general, profitability and risk are two variables that move in the same direction, so that those investments that, a

priori, offer more profitability also involve greater risk. The final decision taken will depend on the individual investor's risk profile. Investors are often risk-averse, so they will prefer to sacrifice profitability favoring greater security. In this sense, sustainable investments are more suitable for most investors, according to the results obtained in most empirical research developed so far. Sustainability reduces the market risk in whatever form it is considered (systematic or idiosyncratic, individual, or market index). Moreover, effective sustainability management enables financial companies to overcome a sudden financial crisis, adds shareholder value, and reduces risk. Nevertheless, for the effects of sustainable policies to be truly successful, they need to be adequately disclosed, both within the company (workers) and outside (other stakeholders).

Description of Sustainability Management and Reporting

Sustainability management and reporting has gained an increasing deal of interest since 1987 when the term “sustainable development” was coined by the World Commission on Environment and Development (WCED) in the report entitled “Our Common Future” and also known as “Brundtland Report” (WCED 1987). The notion and ultimate purpose of this new model of global development has led to a contemporary change in societal values. Besides, organizations feel this pressure in their operations as well. Therefore, to achieve economic, social, and environmental sustainability goals framed by the concept of sustainable development, organizations have taken on their responsibilities to do business with a holistic perspective of integrating social aspects, environmental concerns, and financial interests

and outcomes. Thus, they have adopted sustainability principles into their values, strategies, measurement, and reporting mechanisms. The basis of sustainability reporting has evolved through the developments of financial and non-financial reporting from the early twentieth century onward. The scope of corporate reporting initiatives was limited to financial statements until the 1970s and then expanded by incorporating social auditing and environmental reporting (Fărcaș 2015). Since the 1990s, sustainability reporting has provided information about the organizational performance with a nested emphasis on the contexts of financial, social, and environmental dimensions. A sustainability report is a sign of remarkable organizational efforts regarding its respect and sensitivity to societal and environmental concerns during its operations and practices to make profit and a reputable credential for corporate transparency, accountability, and creating value for stakeholders. Thus, sustainability reporting is considered a measurement of the progress of sustainable business activities and a communication vehicle that presents reliability.

The Concept of Sustainability Management and Reporting

The awareness of the adverse impacts of industrialization, urbanization, and increasing population such as degradation of environment and humanitarian problems such as inequality, injustice of income distribution, and poor quality of life led to the adoption of sustainable development goals with a global consensus. At the organizational level, this awareness makes pressure on organizations to rethink humanitarian and environmental concerns while they operate their businesses. Theoretically, the reason for this pressure arises from stakeholder theory (Freeman 1984) focusing on the relationship between the organization and their shareholders and other interest groups. Accordingly, the quality of this relationship affects the continuity and the performance of the organization (Donaldson and Preston 1995). Although different stakeholders (employees, customers, suppliers, investors, governments, etc.)

may have different demands and expectations and thus they may evaluate the concept of sustainability from different perspectives because of their self-interests or concerns, it is inevitable that stakeholders can be assumed as a pressure group for organizations to pursue sustainability goals in their operations. As a result of this pressure, corporate sustainability has been accepted as a comprehensive concept that requires the simultaneous acceptance and satisfaction of economic, social, and environmental needs and interests of both present and future stakeholders (Van Marrewijk 2003: 101; Dyllick and Hockerts 2002: 131). Thus, developing relationships with stakeholders with sustainability lenses can be assumed as both major assets that should be managed and the primary sources of organizational prosperity.

As a significant milestone in sustainability management, Elkington's (1994) well-known triple bottom line (TBL) approach which argues the reconciliation of economic, social, and environmental standards of an organization has been generated from a 3P formulation that includes people, planet, and profits (Elkington 1997). In this formulation, people represents the social dimension of sustainable development, whereas the planet and profits represent environmental and economic aspects of the concept respectively. Elkington (2004: 3) suggests "seven drivers" – namely markets, values, transparency, life-cycle technology, partnerships, time, corporate governance – that encourage organizations to manage social and environmental concerns together with the economic ones. To him, political and economic communities are going to experience a transition of "global cultural revolution" that will take place with these drivers (Elkington 2004: 3). Third of his seven proposed drivers is transparency. Accordingly, with the transparency revolution, international transparency will increase and, as a result, organizational practices and behaviors will be under scrutiny. Therefore, all stakeholders will be more aware of what is happening in the business world that catalyzes benchmarking and ranking the organizations. The transparency revolution pursue organizations to adopt Elkington's (2004) TBL thinking, planning, and accounting. Derived from the changes and new

developments regarding stakeholder expectations and corporate transparency perspective due to the TBL approach, an increasing number of organizations have transformed from conventional to sustainable practices and integrate sustainability into their values, products, processes, and reporting frameworks as well. Thus, by sustainability reporting, it will be possible to measure the sustainability performance so that it will be more manageable, and at the same time, stakeholders will be informed about the extent to which the corporate activities carried out by the organization are compatible with the sustainability principles and goals.

From Traditional Reporting to Sustainability Reporting

To strengthen organizational performance, and constitute permanent and reliable stakeholder relations, organizations need appropriate measurement and control mechanisms. As a part of these efforts, measurement of the performance and reporting has become remarkable. The history of corporate reporting goes back to the economic transition from a trade-based system to an industrialized system. From the early twentieth century, the American capital market began to expand and attract more investment. Thus, sharing financial and accounting information with all stakeholders has been accepted as a necessity (Fărcaș 2015), but reporting was limited to arbitrary initiatives and contained only financial information. Following the banking crisis experienced in 1933 in the United States, financial reporting became mandatory by the Securities Act of 1933 (Karğın et al. 2013: 30) which was a legal and authorized entity for standardization of the US financial reporting from 1933 to 1973 (Fărcaș 2015: 108) and served as an inspiring milestone to develop new standards of financial reporting at national and international levels. From the mid-1970s, due to the increasing awareness of social and environmental concerns, the concept of social and environmental auditing and reporting has started to gain widespread attention (Gray

2000) and they have been considered in corporate reporting as well. The improvement in the context of traditional financial reporting has continued to proceed toward social accounting and reporting by the 1970s and environmental issues by the 1980s (Hahn and Kühnen 2013). The concept of corporate reporting has gained a new perspective to present comprehensive information more than the numerical, commercial values in financial reports. Therefore, the scope of reporting has expanded including both quantitative and non-quantitative but descriptive information regarding all stages of the value chain. This shift has continued through sustainability reporting as organizations have endeavored to be more sustainable in their operations since the 1990s. To assess sustainability performance, they have been applying several tools and guidelines developed in recent years (i.e., Global Reporting Initiative (GRI) Guidelines, the United Nations Global Compact (UNGC) (n.d.) Principles, Integrated Reporting (IR), and Carbon Disclosure Project (CDP) system) and publishing sustainability reports increasingly.

life should no longer compete, instead a holistic perspective is required to achieve a sustainable future. Thus, to reach sustainable development goals at global level, achieving sustainable development at organizational level has a significant importance. Therefore, the top priority of business professionals in recent years is managing sustainability as the core of the organization. Sustainability management refers to the integration of sustainability-related issues into corporate activities and strategies. To operate in a sustainable way, an increasing number of organizations have applied to several environmental and social management systems that allow measuring, managing, and controlling the environmental and social performance. In recent years, the most widely used of these systems are the International Organization for Standardization (ISO) 14,000 of environmental management system, the European Union (EU) Eco-Management and Audit Scheme (EMAS), Social Accountability (SA) 8000 standards, and Global Reporting Initiative (GRI) standards of reporting. When sustainability is defined as the ultimate purpose of sustainable development, several studies have stated that sustainability management is a challenging process, requires long-term progress, and encourages businesses for change (Kiesner & Baumgartner, 2019; Esquer-Peralta et al., 2008).

Sustainability Management Process

Description

Sustainable development that has become impressive since the 1980s, has reached a consensus that economic, planetary, and humanitarian aspects of

Management and Sustainable Development

In the twentieth century, following the Industrial Revolution, the world has witnessed several economic, social, and political developments. During this century, economic prosperity has increased with revolutionary impacts. Population growth has been recorded after the end of the world wars that shook many countries of the world. Parallel to the industrialization experienced, the population distribution balances started to intensify toward urbanization. On the other hand, the socioeconomic developments experienced in this period have led to some negative environmental and social consequences such as the destruction of natural resources, the rapid consumption of

nonrenewable energy resources, and the protection of the fundamental rights of employees, which are among the most important production factors. These adverse impacts have led to an awareness on handling of economic, social, and environmental issues from a new perspective (Özmehmet, 2008). In line with these developments, sustainable development refers to an extended consideration of economic growth at present without damaging or losing the existing social and environmental resources required by the future generations (WCED, 1987). The concept has a supranational character in terms of the scope of its definition announced by the Brundtland commission and the initial stage of its development. Nevertheless, it has become a concept that is targeted and applied from the global level to the national, regional, and organizational level (Altuntaş & Türker, 2012). The understanding of sustainable development has transferred to the organizational level by means of corporate sustainability that is defined as “meeting the needs of present organizational stakeholders without compromising the organization’s ability to meet the needs of future stakeholders” (Dyllick & Hockerts, 2002, p. 131). In this regard, corporate sustainability, in its simplest sense, indicates the reflection of a sustainability-oriented development perspective onto the corporate level (Altuntaş & Türker, 2012). Whereas sustainable development embodies an ethical, normative, and generic guidance, contributions of the businesses to sustainable development goals become visible through the corporate sustainability management approaches and practices.

Approaches for Sustainability Management Process

Sustainability management process requires a triangular relationship among economic, environmental, and social aspects of the organizational performance. Moreover, sustainability management encourages a transformational process that involves the integration of ecological, social, economic, legal, ethical, and technical dimensions (Angiel & Angiel, 2015; Pawłowski, 2012:

81–82). In this regard, organizations may implement several approaches in order to achieve their own corporate sustainability targets. As sustainability is a comprehensive concept, neither the scholars nor the practitioners agree on a common methodology on how to manage the sustainability management process. Instead, some managers focus primarily on ecological/environmental aspects of the concept, while some professionals predominantly consider corporate social performance. Therefore, management approaches are clustered in the fields of environmental, social, and/or holistic views in parallel to the multidimensional characteristic of the concept of sustainability. Environmental approaches of sustainability management process focus on the conservation of natural resources, air and water pollution, energy use, wastes, greenhouse gas emissions (Diesendorf, 2000), biodiversity, renewable and nonrenewable sources, and fuel usage (AtKisson, 1996). In this regard, ISO 14000 of the environmental management system and EMAS (The EU Eco-Management and Audit Scheme) are implemented for environmental sustainability management processes (Esquer-Peralta et al., 2008). The main concerns of social approaches to the sustainability management process are human rights and social security (Lee & Saen, 2012). Therefore, indicators related to human and labor rights, equal opportunity, non-discrimination, equal remuneration for women and men, security practices, freedom of association, and prevention of child labor practices are frequently stated (Gallego, 2006) for social sustainability management processes. In general, SA 8000 of social accountability standards and ISO 26000 are applied to achieve social sustainability goals (Gilbert & Rasche, 2007). Bringing together the environmental and social focus of sustainability with economic sustainability performance, holistic approach to sustainability management processes make sense. In order to evaluate how much the organization’s efforts have contributed to sustainability, sustainability reporting has a significant importance and, in this regard, GRI standards (GRI, 2022) are used by many organizations throughout the world. Furthermore, many scholars also discuss approaches such as change

management processes for corporate sustainability (Lozano et al., 2015), integrated management systems to support corporate sustainability, and the European Foundation for Quality Management (EFQM) Model for sustainability management process (Akkucuk & Gencer, 2017).

Sustainability Management Process and Value Creation

Sustainability management approaches create value for organizations, regardless of characteristics such as size, location, or sector they operate in. Sustainability management process establishes a nexus between financial and nonfinancial performances of an organization.

In general, sustainability management process enables organizations to mitigate negative environmental, social, and governance impacts, to improve reputation and brand loyalty, to raise awareness for external stakeholders to understand the organization's true value, and tangible and intangible assets, to emphasize the link between financial and nonfinancial performance, and to improve efficiency (GRI, 2022).

As organizations succeed in integrating social and environmental sustainability performance into financial projections and strategic business goals, customer value also extends. The meaning of the concept of customer value in terms of business management is related to the mutual relationship and interaction between the organizations and the customer. In this context, there is a relationship and interaction between the organizations and the customer in terms of sustainability. In today's business world, as the production and marketing strategies of organizations have become more customer-oriented, organizations determine their values and practices considering sustainability perceptions of customers, and customers are informed about their sustainability approaches through corporate communication tools by organizations. The relationship and interaction between organizations and customers brings up the concepts of sustainable customer and sustainable consumption as well

as sustainable organizations (Gilg et al., 2005; Seyfang, 2006).

Furthermore, sustainability management efforts create value for organizations in regard to supply chain management activities. Sustainable supply chains should include not only the profit and loss dimensions of the business, but also the social and environmental dimensions, which are an important performance measure for sustainability and referred to as the triple bottom line (Elkington, 1997; Kleindorfer et al., 2005; Esty & Winston, 2009; Gupta & Benson, 2011).

Fidge and Hahn (2004) put forward the Sustainable Value-Added approach in the evaluation of corporate sustainability performance with a focus on opportunity cost, generally considering the expenditures made to cover environmental or social damages or the value created to measure the organizational contributions of sustainability practices. Accordingly, it is necessary to focus on the difference between created value and resource use. Sustainable Added Value measures how much value an institution creates by simultaneously evaluating the economic, social, and environmental performances of that institution. The reason for this is that each of the three dimensions (economic, environmental, and social) is a separate source of capital and it is not possible to substitute these sources for each other (Figge & Hahn, 2004).

Summary

The United Nations Global Compact (UNGC) aims to create a culture of sustainable development in the business world and to have a desire for all organizations possessing a shared responsibility within their scope of impact. In this regard, organizations need to take action to improve the current situation on human rights, labor standards, ethical standards, and the environment. Recognizing, supporting, and implementing sustainability-related issues in business processes lead to the sustainability management process. In return, negative environmental, social, and managerial effects could be reduced and risks derived from ongoing economic, environmental, and social developments could be better managed.

Sustainability Measurement

Sefer Aydoğan

Military and Social Science Department,
Air Force Academy/National Defense University,
İstanbul, Turkey

Definition

According to Heal (2011), the concept of sustainability indicates a way of doing things which

could continue in the long run without any major consequences. The concept of sustainability has flourished over the last two decades. In the concept of sustainability, the key questions arise from sustaining what, for whom, where, and for how long, to achieve well-being in the long run (O'Connell et al. 2013).

Introduction

In time, businesses started to harm the environment and the society they live in. For this reason, concerns have started to be heard about the present and future of humanity and the environment around the world. The issue of sustainability has come to the fore in order to eliminate these concerns and to carry out business activities without endangering the present and future of society and the environment. Since the sustainability is contextual, the measurement of institutional sustainability has become a subject that has been discussed all over the world since the 1990s, and many researches have been made on this subject. However, since then, there has not been a worldwide accepted measurement method (HUD USER 2021). Yet, measuring sustainability can help to assess the advancement, encourage broad participation of stakeholders, meet or anticipate new requirements, find barriers to the program, and communicate goals. The sustainability is measured by evaluating the performance of social, environmental, and economic principles. This means expanding the traditional business reporting framework. For this reason, many organizations are developing organization-specific or industry-specific measurement tools and best practices (Sustainable highways 2021).

Sustainability measurement is the quantitative basis for the informed management of sustainability. There are two distinct questions: first, how the level of well-being is changing over time, and second, how the level of well-being can be sustained. GDP and its indicators and Human Development Index (HDI) are attempts to answer the first question, the level of well-being, but the

second question leads into a detailed discussion of sustainability. The remarkable example for unsustainability is Saudi Arabia. Even Saudi Arabia has huge oil reserves, and it is not sustainable in the long run (Heal 2011).

There are many approaches to assessing and implementing sustainability. Consensus is emerging that the indicators related to physical, ecological, and economic policies and systems and their interactions which support well-being are fundamental (O'Connell et al. 2013). Sustainability measurement has two forms, weak and strong, which depend on the elasticity of substitution between natural capital and other forms of capital including physical capital, intellectual capital, etc. (Heal 2011).

Measuring Sustainability

The term sustainability assessment where it covers the collection and evaluation of relevant sustainability data is used widely in the literature by policy makers. The complexity of sustainability issues makes sustainable measurement very difficult. Most of the data are inaccessible for private or academic institutions all around the world. The Global Agenda Council on Measuring Sustainability aims to take an initiative, Environmental Big open Data Initiative (EBODI). The conceptual changes in sustainability result the need to consider disparate data, varying scales, and methodologies to evaluate complexity of sustainability (O'Connell et al. 2013).

The sustainability data sets can range from relatively simple variables (e.g., temperature) to relatively complex variables (e.g., metrics which describe forest fragmentation and risks to biodiversity). There are also several variables referring to the sustainability discourse which cannot be quantitatively measured (e.g., climate vulnerability, food security, and sustainable competitiveness) (O'Connell et al. 2013). Sustainability indicators point at the links among the economic, social and environment. Traditional indicators are based on the economic and environmental indicators such as stock holder profits, gross domestic

product (GDP), water availability, pollution, production factors, and other natural resources indicators. For example, the GDP as a traditional economic indicator measures the overall economic well-being of a country. However, GDP refers the monetary level of economic activity and fails to explain sustainability dimensions such as environmental health of a country. At this point, the index of sustainable economic welfare (ISEW), a sustainability comparable indicator provides a more complete picture on the sustainability issue. For instance, the ISEW accounts for air pollution by estimating the cost of damage or approximates the cost of climate change due to

greenhouse gas emissions per ton of emissions (Sustainable measures 2019) (Table 1).

Sustainability Measurement Requires

- Determining and monitoring key sustainability measurement variables and indicators that are relevant to sustainability issues and problems
- The generation of suitable model-based data and projections across scales
- Addressing the absence of relevant theory regarding sustainability in linked socio-economic policies and systems

Sustainability Measurement, Table 1 Traditional indicators versus sustainable indicators

Traditional indicators	Sustainability indicators	Emphasis
Economic indicators		
Median income Per capita income relative to the US average	Number of hours of paid employment at the average wage required to support basic needs	What wage can buy defines basic needs in terms of sustainable consumption
Unemployment rate Number of companies Number of jobs	Diversity and vitality of local job base. Number and variability in size of companies. Number and variability of industry types. Variability of skill levels required for jobs	Resilience of the job market. Ability of the job market to be flexible in times of economic change
Size of the economy as measured by GNP and GDP	Wages paid in the local economy that are spent in the local economy Dollars spent in the local economy which pay for local labor and local natural resources. Percentage of local economy based on renewable local resources	Local financial resilience
Environmental indicators		
Ambient levels of pollution in air and water	Use and generation of toxic materials (both in production and by end user). Vehicle miles traveled	Measuring activities causing pollution
Tons of solid waste generated	Percentage of products produced which are durable, repairable, or readily recyclable or compostable	Conservative and cyclical use of materials
Cost of fuel	Total energy used from all sources. Ratio of renewable energy used at renewable rate compared to nonrenewable energy	Use of resources at sustainable rate
Social indicators		
SAT and other standardized test scores	Number of students trained for jobs that are available in the local economy. Number of students who go to college and come back to the community	Matching job skills and training to needs of the local economy
Number of registered voters	Number of voters who vote in elections. Number of voters who attend town meetings	Participation in democratic process. Ability to participate in the democratic process

Source: Bueno 2009

- Estimating impacts of sustainability policies and implementations
- Developing quantitative methods and approaches for assessing trade-offs between different sustainability dimensions (O'Connell et al. 2013).

Four Key Building Blocks in Sustainability Measurement

O'Connell et al. (2013) indicate four key building blocks as essential in sustainability measurement:

- Data: specification, collection, elimination, modeling, and analysis as the basis for measurement
- Evaluation: interpreting the data in relation to sustainability objectives
- Feedback: providing information to promote sustainable development
- Institutional or policy mechanism: formal and informal rules and policies to implement the sustainability framework by the policy makers

Various Approaches Which Support Sustainability Measurement

Within the literature, different disciplined fields of study are critical for addressing the concept of sustainability:

- Discipline-based science: economics, ecology, hydrology, agronomy, etc., which provide knowledge about different dimensions of sustainability (e.g., climate, biodiversity, agriculture, fisheries, forests, energy and resources, water, economic development, health, and lifestyle)
- Place-based: multidisciplinary and interdisciplinary approach to examine sustainability issues and their interaction within a particular region
- Integrative approaches: problem-based approaches, goal-oriented approaches,

solution-based approaches, etc. (O'Connell et al. 2013).

Key Issues

Patterns that are not probably sustainable in the long run (Heal 2011):

- Energy resources
- Water availability
- Species
- Forests
- Fish population
- Bioenergy production
- Agricultural production that is also threatened by the climate change and pollution

Thus, sustainability requires the sustainability of natural capital.

Summary

The sustainability measurement is the quantitative basis for the informed management of sustainability. Due to the fact that the main purpose of the sustainability measurement indicators is to inform public policy-making, the sustainability indicators can provide information on any aspect of the interplay between the environment and socio-economic activities. Therefore, they involve indicators, benchmarks, audits, indexes and accounting, assessment, other reporting systems. They can be performed at a wide range of spatial and temporal scales. The sustainability measurement metrics are still advancing.

Sustainability of Boards

Borna Jalsenjak

Luxembourg School of Business, Luxembourg,
Luxembourg

Zagreb School of Economics and Management,

Synonyms

Environmental concerns; Governance concerns of the board of directors; Social concerns

Definition

The concept of sustainability of boards is an umbrella term covering issues connected to how boards of directors impact and should affect the environmental, social, and governance issues.

Introduction

In the context of the sustainability of boards, sustainability is most often connected to environmental, social, and governance concerns that boards of directors should pay attention to. These concerns are usually summarized using the acronym ESG.

ESG – Environmental, Social, and Governance Concerns

Each of the elements of ESG, environment, society, and governance, has a multitude of elements. For example, in the environment category, organizations might look at things like gas emissions or wastewater disposal. Regarding the social element, things like worker rights, labor unions, or diversity are the topic. Finally, in terms of governance, things that can become a topic include board composition, relations with stakeholders,

and ethical processes and policies. Looking at ESG from an overarching perspective, those issues gather all the standard elements of corporate social responsibility. Each of the mentioned topics influences how the public perceives organizations because they are becoming more important for stakeholders. They are often found on the list of priorities or concerns.

For example, in the World Economic Forum Report for both 2018 and 2019, the environmental risks are firmly placed in a highly impactful and highly likely risk category (Collins 2018, p. 3; 2019, p. 5). This means that they should not be ignored by the board of directors responsible for the organization (Deloitte 2018). Social concerns are high on the stakeholders' list of interest as well. Governance topics have also been in much focus. For example, researchers have tried to answer how is the board composition and size related to corporate social performance and sustainability (Ortiz-de-Mandojana and Aragon-Correa 2015; Rao and Tilt 2016; Zubeltzu-Jaka et al. 2020) or how can boards influence sustainability initiatives in organizations (Galbreath 2012; Sanchez et al. 2017). These are just examples, but the main points that are coming across are that boards are important agents when considering sustainability issues. To summarize, stakeholders seem to pay more and more attention ESG concerns and risks, or in general terms, to sustainability, so the boards need to pay attention to those issues (Galbreath 2012).

Furthermore, paying attention to ESG concerns is not only a request coming from the general public; there are also requests from the regulatory bodies that specific companies that are considered as being of public interest should file nonfinancial reports. In the EU for example, companies over 500 employees which are designated as public interest companies need to disclose information on environmental protection; social responsibility and treatment of employees; respect for human rights; anti-corruption and bribery; and diversity on company boards (in terms of age, gender, educational, and professional background) (Directive 2014/95/EU 2014). All elements of the nonfinancial reporting mentioned

by the EU fall firmly within the context of the ESG concerns.

Sustainability and Boards

Usually, if something is not in the focus of the organization's board of directors, then it will not be in that organization's strategy. In his literature review, Minciullo (2019, pp. 29–30) emphasizes that the board of directors impacts the integration of sustainability in strategy. Moreover, he goes on and expands by highlighting elements that have been found to have a significant impact on sustainability. Those elements are board composition, diversity, and having a board committee in charge of environmental issues (Minciullo 2019, p. 30). Besides a wide variety of academic literature on the subject, the sustainability of boards is also a frequent topic in professional journals and publications. In that type of literature, authors describe, for example, how boards can take advantage of the risks that sustainability entails, how and what should be done by boards to support sustainability initiatives in organizations, or who should be on the board of directors to achieve optimal results (Deloitte 2018; Lawler and Worley 2012; Smith and Soonieus 2019; Spitzer and Mandyck 2019). Again, as before, these professional papers point to the same topics as academic journals.

Summary

As described above, the sustainability of boards is an overarching idea that looks at how boards of directors approach sustainability issues that encompass ESG issues. Research branches off in many directions on the impact that boards can have in the context of sustainability initiatives in organizations. Besides academic interest, the board's role and responsibility regarding sustainability are topics of many professional publications. All are emphasizing that board involvement is important in dealing with sustainability concerns.

Sustainability of Waste Management System: Environmental Impact Management with Life Cycle Assessment

Jouni Havukainen, Ivan Deviatkin and
Mika Horttanainen
Department of Sustainability Science,
Lappeenranta-Lahti University of Technology
LUT, Lappeenranta, Finland

Definition/Description

Increased global concern on the state of our climate, water, and soil have driven the waste management sector to look for technical solutions that enable lowering of the environmental impacts. This has led to investigations on the environmental impacts of waste management systems for which life cycle assessment (LCA) has been widely used. The LCA methodology is a standardized approach and the principles and general guidelines are laid down in the ISO 14040 and 14044 standards. The main aim has been in comparing different treatment methods and with 1 t of municipal solid waste (MSW) as a functional unit (FU). LCA can be utilized as a support for investment or development decisions, in research and development as well as in providing information for decision makers. Two main MSW treatment technologies, which have been investigated the most, are landfill disposal and incineration. In general, landfill disposal is less favorable than waste incineration, while the operation environment and technological advancement have a large impact on the net results. However, the LCA studies on MSW management to date have mostly focused on European or Asian countries (and to some extent in North and South America) while a large share of nations have not a single MSW management LCA study.

Introduction

The development of waste management sector has been driven by the development of human

settlements in general. In the era of humans and humans living in hunter gatherer bands, the “waste” was dispersed on a wider area and mainly what remained were bones from the hunted animals. The age of agriculture brought with it larger pockets of human settlements, and waste generation started to concentrate. However, the waste as a stressing problem became more evident with the industrial age and larger cities with limited space for the waste. The transport of waste to further away became a necessity and landfills started to be formed. At present, in the age of information technology with the increased global concern on the state of our climate, the development of waste management sector is driven by the determination to look for technical solutions that enable the applied circulation of materials at the same time when safe treatment of waste and avoidance of environmental hazards is still very important.

The construction and mining sectors are among the main contributors to the waste generation. In the 28 EU countries the share of construction waste was 36% and mining industry 25% of the total waste generated in year 2016, Fig. 1, which was 2500 million tonnes. The treatment of this generated waste in EU-28 countries in 2016 was heavily dependent on landfilling with a share of 45.5% of the generated waste. However, EU is globally the most developed continent in the field of waste management and recovery. The share for recycling was 37.5%, backfilling 10.1%, energy recovery 5.6%, and incineration without energy recovery 1%.

The waste management is regulated by national and international legislation. In the EU-28 region the waste framework directive (2008/98/EC) lays down the concepts of waste and concepts for recycling and recovery. The directive presents the principle of organizing waste management in such a manner that it does not endanger the human health or pose adverse impacts on the environment. It also introduces the waste hierarchy, which has been adopted in many national legislations. There are also directives for specific waste management options, for example, if waste is to be landfilled, the landfill should be in compliance with the landfill directive (1999/31/EC) or if waste is going to incineration the emission should be minimized in accordance with the

Sustainability of Waste Management System: Environmental Impact Management with Life Cycle Assessment,

Fig. 1 The generation of waste by economic activities and households in 2016 (Eurostat 2018)

waste incineration directive (1991/31/EC). The national legislation can then have more strict requirements for waste management such as land-fill bans on organic municipal solid waste (MSW), for example, in Germany, Denmark, Sweden, and Finland.

The waste hierarchy proposes the preferred order of measures taken for waste and waste management. Firstly, where possible, the waste reduction measures should be enforced. When this is not possible, the reuse of waste should be preferred after which material recycling is the next on list of treatment options followed by energy recovery of waste and lastly safe disposal of waste. In the age of circular economy, also the waste management is more in the spotlight and strict aims for enhancing recycling have been laid down, especially in EU. The efficient source separation of waste is the single most effective measure to obtain suitable materials for waste recycling but in some cases, this is not possible and mechanical sorting is required to obtain waste fractions for recycling. The aim in recycling of the waste is to reduce the need for utilizing virgin materials in making of the new products, which reduces the environmental impacts.

To estimate the environmental impacts of waste management a systemic way for calculating the environmental impacts is required. Environmental impacts of waste management systems have been widely assessed by utilizing life cycle assessment (LCA). LCA is a widely adopted method for calculating the environmental impacts

of products and various production systems. It has been successfully adopted for acquiring information for the decision makers also in waste management sector.

This entry of the encyclopedia focuses on the environmental impact management of waste management systems. The basic principles of LCA are presented while focusing on the specific aspects of environmental impact evaluation of waste management systems, more specifically to LCA of MSW management, which has a plethora of management options.

Application of Life Cycle Assessment to Analyzing the Environmental Impact

The environmental impact analysis utilizing LCA is as standardized approach and the principles and general guidelines are laid down in the ISO standards 14040 and 14044 (ISO 14040 2006; ISO 14044 2006). In addition, carbon footprint calculation, a widely used special application of LCA, considering only global warming potential is described in standard 14067 (ISO 14067 2014) and further information is provided in PAS 2050 (British Standards Institution (BSI) 2011) and greenhouse gas (GHG) protocol (Greenhouse Gas Protocol 2011).

The LCA procedure consists of four main phases, the order of which is described in Fig. 2. However, the LCA is an inherently iterative process where the output of a given phase may result

Sustainability of Waste Management System: Environmental Impact Management with Life Cycle Assessment, Fig. 2 The four main steps in LCA. (Modified from ISO 14040 2006)

in a need to return to the earlier phases of the LCA. The starting point is the goal and scope definition where the aim of the study as well as the function are clearly described, which are then used to define the system boundary that encompasses the relevant processes and the functional unit (FU). The FU is needed because LCA methodology is a relative approach and all subsequent analysis are related to the selected FU. The life cycle inventory analysis (LCI) phase entails the gathering of all the relevant input and output data of the processes included inside the system boundary. This includes, for example, the used materials, energy, as well as the produced products, waste, and other generated emissions from a given process. The LCI data is then utilized in the life cycle impact assessment (LCIA) phase to ascertain the environmental impact by associating the data with the selected impact categories. The LCIA includes mandatory phases optional phases, which are summarized to Fig. 2.

In LCA study, there are usually situations where the production system under study has more than one output product and there is a question how to calculate the environmental impact of the product under investigation. One possibility is to conduct allocation between the products.

However, according to standard ISO 14044 (2006), allocation should be avoided if possible by dividing the unit processes or by using system expansion. When allocation cannot be avoided, it should in the first place be done based on physical properties (mass, energy content), and if this is not possible, by some other means, which reflect the relation of the products such as economic value. For example, in an article by Havukainen et al. (2018), allocation between biogas and produced composted digestate was conducted in order to calculate the carbon footprint for nitrogen and phosphorus included in the compost. Mass-based or energy-based allocation would not have been optimal in allocation emissions between gaseous energy carrier and solid fertilizer product, which meant that economic values were used.

In some cases, it is possible to expand the system boundary to include several production systems. One example is comparison of waste landfilling scenario to a scenario where waste is directed to incineration. The main aim of both scenarios is managing of the waste, but waste incineration also produces heat and electricity, which might not be produced in the landfilling scenario, which makes straight comparison of the scenarios difficult. One option is to include

in the landfilling scenario emissions from additional production of equivalent amounts of heat and electricity, as in incineration scenario, from alternative sources, as is shown in Fig. 3 with system boundary 1 (additional production). This option was selected by Uusitalo et al. (2014) and similar quantities of products in all scenarios. Another option is to include in the incineration scenario the avoided emissions from displacing electricity and heat generation from alternative fuel sources by subtracting these emission from other emissions generated in the scenario, which is shown in Fig. 3 with system boundary 2 (avoided production). Liikanen et al. (2018) included the avoided emissions from displacing electricity and material products when comparing MSW management scenarios for Sao Paulo city and similar option was selected by Deviatkin et al. (2017) when comparing the different options for recycling of thermal residue in South Karelia region. The difference between additional and avoided production methods is only in the way the results are calculated and presented, since the

difference in net results between scenarios will be the same with both methods.

In the waste management LCA studies, the assumption of zero-burden condition is usually applied to the waste fractions (Laurent et al. 2014), which means that the waste coming to the studied system boundary does not carry the environmental burdens from the previous stages of life cycle. With such an approach, the system boundaries usually begin with the impact from collection and transportation of waste to the studied disposal facilities. The assumption of zero-burden condition is suitable when comparing different waste management options since the upstream emissions would be similar for all the assessed options and those parts, which are similar can be disregarded in a study where different treatment options are compared (Finnveden 1999). However, in case when the input waste amount to compared systems are not similar, for example, due to waste prevention actions in some of the compared waste treatment scenarios, the system boundary should, in principle, be drawn to include

Sustainability of Waste Management System: Environmental Impact Management with Life Cycle Assessment, Fig. 3 Two system boundaries with

additional production (1) and avoided production (2) (European Commission – Joint Research Centre 2010)

the upstream processes as stated by, for example, by Djuric Ilic et al. (2018). It is also important to investigate if the input materials should be considered waste or coproduct since according to ISO 14044 (2006), the outputs and inputs would be allocated only to coproducts.

Examples of LCA Studies on MSW Management

LCA has become an established means for investigating environmental impacts also in waste management sector and several studies have been conducted in different operating environments around the world. Khandelwal et al. (2019) conducted a review on 153 LCA studies concerning MSW management, most of which were concerning Europe or Asia and high-income countries (and to less extent in North and South America), while there were several countries from which there were not a single LCA on MSW management. The main waste management technologies, which were investigated in the studies were landfill disposal and incineration followed by mechanical treatment and biological treatment with the most common FU being 1 t of MSW. A few examples about the LCA conducted in MSW management in different operation environments and selected goal and scope, FUs, technologies as well as environmental impact categories are presented in Table 1. The impact assessment results of these studies are summarized in chapters Environmental Impact Assessment of MSW Management of Hangzhou, changes in Environmental Impacts from Improving MSW Management in Sao Paulo and Greenhouse Gas Emissions of MSW Management Options in South Karelia.

Environmental Impact Assessment of MSW Management of Hangzhou

The environmental impacts of waste management in Hangzhou were studied by Dong et al. (2014) and more recently by Zhou et al. (2018). In the study by Dong et al. (2014), the comparison was made between landfill disposal without LFG collection, landfill disposal with energy recovery from LFG and incineration. The LFG collection

and energy recovery scenario already reduced the GWP by 74% to 300 kg_{CO₂,eq.}/t MSW from 1100 kg_{CO₂,eq.}/t MSW, which is generated in scenario without LFG collection. This is due to the high assumed collection rate of LFG, which was 70%. The incineration scenario then resulted in GWP of 200 kg_{CO₂,eq.}/t MSW, which is then 30% less than the scenario with LFG to energy scenario. In the study by Zhou et al. (2018), the mixed MSW management in Hangzhou comprised of five incineration plants and one landfill. The main treatment options were also landfill disposal and incineration, while there was also separate landfilling of food waste and to small extent also directing of food waste to anaerobic digestion. The LHV_{ar} of MSW was low 5.6 MJ/kg, which meant that coal was used as auxiliary fuel and collection rate of LFG was assumed to be 65%. Directing waste to incineration reduces the GWP by 46% to 271 kg_{CO₂,eq.}/t MSW from 502 kg_{CO₂,eq.}/t MSW.

Changes in environmental impacts of waste management system in Hangzhou by RDF production from waste for a waste-to-energy plant in comparison to untreated waste incineration were investigated in work done by Havukainen et al. (2017). The waste management comprised of two landfills and four waste incineration plants. The main characteristics of the study region waste management were that there was no effective source separation of biowaste, which meant that the lower heating value as received (LHV_{ar}) of waste was low, only 4–5 MJ/kg. This meant that coal was used as an auxiliary fuel in the waste incineration plants and it was assumed that this coal would not be needed if RDF would be produced. Another trait in the region was that waste-to-energy plants were only producing electricity since district heat is not consumed in the region. There was also relatively low landfill gas (LFG) recovery rate of 30% in the main landfill of the region, while on the other one there was no recovery.

The main findings in the study by Havukainen et al. (2017) were that RDF production from waste can reduce the emissions from the MSW management but the benefits greatly depend on the subsequent treatment of organic reject from the RDF

production. Reductions to GWP of waste management were not obtained when organic reject was directed to landfill, but if organic reject would be dried and directed to incineration, emissions could be reduced by 10% and if reject would be directed to anaerobic digestion or ethanol production the emission reduction could be 20%. The impact of organic reject treatment can be more significant than improvement in electric efficiency, since improving the electric efficiency of waste-to-energy plant from 24% to 32% reduced the emissions of the studied system by 14%, while changing the treatment of organic reject from landfill disposal to anaerobic digestion reduced the GWP by 20%. For acidification and eutrophication potential the impact of organic treatment was even greater, since if organic reject is directed to landfill or incineration the emissions were increased while directing them to anaerobic digestion or ethanol production reduced the emission from the waste management system. However, the main improvement in the waste management would be obtained from improving source separation of food waste and proper utilization of it, for example, in anaerobic digestion. This would reduce the LFG production if the waste is directed to landfill and improve the LHV_{ar} of waste, which would improve the energy recovery from waste-to-energy plant.

The LCA studies by Dong et al. (2014) and Zhou et al. (2018) have been made in a more traditional way by comparing different treatment options, namely, landfill disposal and waste incineration. The aim of their studies is to find out what environmental benefits could be gained by improving the landfill technology or transitioning away from landfill disposal to waste incineration. The study by Havukainen et al. (2017) focuses more on developing the present waste management situation, which includes both waste disposal and waste incineration. The focus is on improving the properties of waste to avoid coal consumption as alternative fuel. This causes a change of flows between landfill disposal and waste incineration since more waste is directed to waste incineration plants to replace coal. These two studies show that you can have a different approach in assessing the waste

management development even in the same regional setting. The studies by Dong et al. (2014) and Zhou et al. (2018) focus on a larger change in waste management, which might take a longer period to realize, while the study by Havukainen et al. (2017) focuses on a more subtle change, which is considering the improvement of the current waste management options and taking into consideration the limitations and possibilities of the current waste.

Changes in Environmental Impacts from Improving MSW Management in Sao Paulo

Changes in environmental impacts by a stepwise improvement of MSW management in Sao Paulo were investigated by Liikanen et al. (2018). The baseline situation was that mixed MSW is sent to two landfills in Sao Paulo. The steps to improve the situation were first to increase slightly home composting (5% of organic waste), second to introduce source separation of organic waste (20%) to composting or anaerobic digestion in addition to home composting, and finally on top of these improvements directing 18% of MSW to mechanical treatment and subsequent utilization of RDF in incineration or cement plant. Increasing the home composting slightly had only a minor impact on GWP with 1% reduction in comparison to landfill disposal (baseline 278 kgCO_{2,eq}/t MSW). Source separation of organic waste and directing it to anaerobic digestion provided higher emission reduction of 11% GWP, while adding mechanical treatment of waste and incinerating the produced RDF resulted only to 1% emission reduction. This was caused by low emission reductions from displaced average electricity, which was mainly based on hydropower and high collection rates for LFG, 80% for one landfill, and 64% for the other one. Highest GWP reduction of 40% was achieved when RDF was directed to cement kiln to replace coal.

The improvement steps in Sao Paulo were selected in such a manner that they could be realistically realizable one after the other with some years in between the steps. The imperfectly working source separation, mechanical sorting, and other practical factors have been considered in selecting the development steps. The

stepwise approach allows for quantifying the improvements in environmental performance, which can be reached with smaller steps in the development of waste management.

Greenhouse Gas Emissions of MSW Management Options in South Karelia

The study by Hupponen et al. (2015) focused on investigating how GHG emissions could be taken into consideration when conducting a tendering process for waste management procurements in South Karelia. The landfill disposal scenario was compared to three waste incineration scenarios: incineration in grate furnace two different locations or fluidized bed boiler after pretreatment in third location. All the scenarios had lower GWP than the landfill scenario with the scenarios including grate incineration had highest reduction of 110–140%. The differences between the two grate furnace scenarios was that grate furnace with higher reduction had higher total annual efficiency because part of the heat was used as steam in process industry, when district heat can be utilized effectively only in cold seasons. The fluidized bed incineration scenario had lower GWP reduction potential of 40% since the substituted district heat near that plant was mainly produced from biofuels.

In South-Karelian case, the landfill disposal and incineration are compared in a regional setting. The different incineration technologies available within reachable distance are considered as well as regional aspects in utilizing the energy produced from waste. The aim was to produce as realistic information as possible from the environmental impacts of the different available options as well as factors that affect the environmental performance. The idea behind is to show what kind of information could be provided by LCA for the public procurements related to waste treatment options and locations, which traditionally are mainly decided by economic factors.

Conclusions from the MSW Management LCA Studies

The summarized LCA studies in chapters 4.1–4.3 show that LCA can have a variety of usages in environmental impact assessment of waste

management. Study by Havukainen et al. (2017), Dong et al. (2014), and Zhou et al. (2018) mainly focused on the comparison of technologies, while the study by Liikanen et al. (2018) investigated the impact of stepwise development of waste management and Hupponen et al. (2015) wanted to discover how decision making about MSW procurement could take GHG emissions into consideration.

The environmental impact results (GWP, AP, and EP) of two main MSW treatment technologies, namely, landfill disposal and incineration, in few selected LCA studies are summarized to Table 2. In addition to studies presented in chapters Environmental Impact Assessment of MSW Management of Hangzhou, changes in Environmental Impacts from Improving MSW Management in Sao Paulo and Greenhouse Gas Emissions of MSW Management Options in South Karelia, results of few additional studies are presented. The large variation in the results in different regions highlight the importance data related to the study region in addition to data related to technological performance. The studies of Manfredi et al. (2009) and Astrup et al. (2009), which consider a range of input data without a specific regional data, show that the variation can be quite significant. In general, landfill disposal is causing more environmental impacts than incineration, but the operating environment has a significant impact on the results. In the study by Hupponen et al. (2015), both heat and electricity from waste-to-energy plant are utilized and displace other energy production while in study by Havukainen et al. (2017) and Liikanen et al. (2018), only electricity could be utilized, which was one of the main reasons for lower GWP in study by Hupponen et al. (2015). The displaced energy has also a huge role in the results since, for example, in study by Liikanen et al. (2018) displaced average electricity was mainly renewable based and this led cement kiln usage to replace coal, which resulted in the lowest GWP. The technological advancement had also high impact on the GWP, for example, low collection rate of LFG (30%) in the study by Havukainen et al. (2017) was the key factor in higher emissions in comparison to results by Liikanen

et al. (2018) where collection rate was much higher (64–80%). The landfill gas yield is another significant factor, which changes according to waste composition. Furthermore, the general uncertainties, inaccuracies, and assumptions affect the results.

In general, in the development of waste management, the policy actions and citizen perception and participation in waste source separation affect the waste management as well as the operating environment. For example, landfill ban on organic waste in Finland had a large impact on waste management and the share of waste incineration increase with the expense of landfill disposal while the share of recycling has not increased yet as much. The increase in renewable energy generation will also affect the LCA results in the future (even during the lifetime of the waste-to-energy plants) by affecting the emission

reductions from displaced energy. However, there are regions where the biggest challenge is caused by the steep increase in waste generation. For example, in larger cities in China, the waste generation rate is still increasing rapidly, which causes huge pressure on the development of waste management. Along with limited space for landfill disposal, it means that waste incineration must be utilized more. The source separation would improve the situation notably but the education of citizens and changes in mindsets takes time.

Summary

LCA is an effective way to quantify the environmental impacts in the waste management sector. The methodology has been standardized and guides for its use have been developed to further

improve the quality of LCAs. In the LCA studies concerning MSW management, the main FU has been 1 t of treated MSW, and majority of the studies have been focusing on the European or Asian location. From the impact categories used in the LCA studies on MSW, the GWP was most used.

The example cases highlight the fact that LCA can be applied to waste management studies in a multitude of ways. Perhaps the most traditional manner to use LCA in waste management is to compare different treatment options to show the impact of complete change in the waste management. LCA can also be utilized to show the impacts of more subtle changes in the waste management system resulting from introduction of improvements to the present situation in the case region or in quantifying the achievable environmental benefits of stepwise development with realistic boundary conditions. In addition, LCA is a useful tool for assessing the impact that the selection of the waste treatment location has on environmental impacts, due to differences in operational environment, such as options for utilizing the produced energy.

Mechanical treatment; Separation technologies

Definition/Description

Increased global concern on the state of our climate has driven also the waste management sector to look for solutions that enable lowering of the environmental impacts by increasing waste reduction and material recycling. Material recycling is more feasible and efficient when there is source separation in place because source separation usually leads to the best quality of the separated materials. However, sometimes source separation does not work properly (e.g., because of the low education level of people) or it is difficult to apply (e.g., because of a fixed and dense city infrastructure). The strict material recycling targets in the EU necessity that mechanical separation is included as a tool for increasing the recycling rate. The aim of the mechanical treatment is to separate materials suitable for recycling from the mixed waste stream by separating recoverable components and impurities to different streams. A multitude of processes is usually required to obtain recyclable materials out of the mixed waste stream, for example, from mixed municipal solid waste (MSW) or mixed construction and demolition waste (C&D waste). However, it should be borne in mind that often the most important factors from the environmental impacts point of view for recovery of materials by mechanical treatment are yield of recoverables,

quality and demand of recovered materials as well as the environmental impact of replaced virgin materials. At the end of the day, the tightened recycling rates strive for the development of various treatment and separation technologies and their better performance is achieved.

Introduction

Increased global concern on the state of our climate has driven the waste management sector to look for technical solutions that enable the lowering of the environmental impacts. The goal, especially in the EU, has been to firstly reduce the waste generation as much as possible. This is achieved by striving to design products and services according to the circular economy concept that support the goal of waste reduction as well as the efficient recycling at the end of life (EoL) of the product. Only as a last resort should there be a safe disposal of waste.

Legislation lays down the definitions and regulations guiding the development also in waste management sector. In EU-28, the overarching legislation is provided by the waste framework directive (2008/98/EC). Waste framework directive, among other legislative acts, provides the basis for measures to be taken in waste management with the waste hierarchy stating as the preferred approach to be waste reduction and after that recycling.

The source separation of waste is the most efficient way to get waste materials suitable for recycling. Source separation is never perfect because there are always people who are not willing or able to do the separation work. Although there are impurities in the source separated fractions, they have a higher share of desired materials than the outputs of mechanical treatment. However, source separation is not possible in some cases due to various reasons and efficient mechanical treatment is needed to obtain waste fractions for recycling and to complete the separation of different materials out of the mixed stream in order to facilitate the increase in the recycling rate.

The tightening goals for recycling rates are justified by the anticipated lower environmental impacts from waste management. Often, the separation and pretreatment processes themselves do not make very large impacts compared to the impacts of utilization or avoidance of landfilling. For example, when it is possible to improve the fuel properties of waste to reduce the auxiliary coal need the environmental benefits are evident (Havukainen et al. 2017). In some cases, however, if disposal of the waste material would not cause large environmental impacts and if recovery of it either does not replace environmentally intensive materials, the mechanical treatment phases can make a large contribution to the whole life cycle impacts (Deviatkin 2017). In such a case, it is possible that treatment causes more environmental impacts than can be achieved benefits with the recovery of that material.

This entry of the encyclopedia focuses on the mechanical treatment and separation of usable materials from mixed waste streams. The basic principles of mechanical treatment, as well as the treatment processes, are presented. Besides, mechanical treatment of waste to produce solid recovered (SRF), preparation from waste, and mechanical separation of plastic waste are discussed in more detail.

Technologies

The aim of the mechanical treatment is to separate materials suitable for recycling from the mixed waste stream by separating recoverable components and impurities to different streams (Gundupalli et al. 2017). A multitude of processes is usually required to obtain recyclable material out of the mixed waste streams, for example, from mixed MSW or mixed C&D waste. The first step usually is size reduction to separate entangled materials from each other, as well as reduce the particle size, thus facilitating the efficient separation of materials in subsequent processes. The following material separation can include separation based on particle size, density-based separation, magnetic separation, etc. Figure 1 presents a simplified chart with the possible treatment phases

Sustainability of Waste Management System: Treatment and Separation for Material Recovery,

Fig. 1 Simplified chart of possible waste separation steps and possible technologies or devices suitable for the separation step

and suitable technologies or devices which can be used in the different treatment phases.

The mechanical processes are not recovering 100% of the desired material from the mixed waste, neither they produce 100% pure fractions of the separation which means that the efficiency of the processes is never ideal. The purity rate, the recovery degree, and the overall efficiency are used to describe the efficacy of the separation processes to perform separation of desired fractions from the reject fractions.

Figure 2 presents a simplified flowchart of mass flows of a separation process. These mass flows can be used to calculate the purity degree, the recovery degree, as well as the efficiency of the separation.

There are almost always some impurities in the fraction which has been separated for the recovery purposes. For example, when separating metals from a mixed flow, the separated metal fraction

can include, e.g., wood fixed in the demolished nails or plastic coverings of metallic pipes. The purity degree (P) can be used to calculate the recoverable percentage of material from separated total mass flow (for example, from underflow).

$$P_{X1} = \frac{X_1}{X_1 + Y_1} 100\% \quad (1)$$

where

X_1 = mass of wanted material to be separated
 Y_1 = mass of other material unintentionally separated from the input mass

The recovery degree (R) shows the percentage of the separated recoverable material from the input recoverable material.

$$R_{X1} = \frac{X_1}{X_0} 100\% \quad (2)$$

Sustainability of Waste Management System: Treatment and Separation for Material Recovery,

Fig. 2 Simplified flowchart of separation mass flows

Sustainability of Waste Management System: Treatment and Separation for Material Recovery,
Table 1 Material recovery efficiencies of selected separation technologies (McDougall and White 2001)

Technology	Separating	Efficiency (%)
Magnet separator	Ferrous metal	60–90
Eddy current separator	Nonferrous metal	60–90
Disc screen	Particulates	50–90
Trommel screen	Particulates	80–90
Vibrating screen	Particulates	60–90
Air classifier	Heavy and light fraction	60–90

where

X_0 = mass of wanted material in the input stream

The efficiency (E) combines both purity and recovery degree and provides an overall efficiency of a given separation technology.

$$E = \left| \frac{X_1}{X_0} - \frac{Y_1}{Y_0} \right| 100\% \quad (3)$$

where

Y_0 = mass of other material in the input stream

There is a wide range of recovery efficiencies for the separation technologies, which can be seen from Table 1.

Particle Size Reduction

Particle size reduction is needed to reduce the particle size and to some extent help separate the entangled materials from each other. The main aim is to enable the separation of materials from each other in the subsequent processes (McDougall and White 2001). After the treatment, the material has more homogenous particle size distribution while the bulk density is not necessarily changing. Commonly used equipment includes hammermills, impact crushers, cutters, cascade mills, and jaw crushers. The factors that affect crusher selection include (Tchobanoglous et al. 1993):

- Properties of the material to be processed
- Feeding method of the crusher
- Criteria for the produced particle size distribution
- Desired properties of the processed material
- Desired usage of the processed material
- Equipment placement circumstances
- Transport and storage circumstances of the crushed material

Hammermills are commonly used for crushing EoL vehicles (ELVs), C&D waste, especially if C&D waste contains concrete, bricks, and other hard inert materials, as well as commercial and industrial waste (C&I waste). Hammermill consists of metal bars or plates that act as hammers which are mounted on a horizontal or a vertical shaft. The hammers hack the material against a crushing wall with a rotational speed of 700–1200 rpm. Increasing the number of hammers enables the production of small particle

size while causing a reduction of the feeding rate (Christensen 2010). There is a grate with a certain size of slots, through which the crushed particles drop out from the hammer mill. The size of the slots determines the maximum particle size coming out from the mill. Flail mills are like hammermills, but the material is not forced through a grate and hammers are further from each other. The processed material from hammermill and flail mill has heterogeneous particle size distribution, while hammermill has smaller output particle size distribution. It is also possible to use shredder which has, for example, teeth attached on one shaft providing a robust shredding of, for example, C&D waste as in Fig. 3.

Cutting shredders are based on the rotating and intersecting blades that are placed between each other on a shaft with a rotational speed of approximately 60–190 rpm and an option for changing the rotation direction. These can be used for different kinds of waste but especially for stretchy and high-tensile materials as well as bag rippers. Shredders are often used for size reduction of MSW and to some extent also to C&D waste if it is mostly containing wood, plastic, and cardboard.

Screening

During the screening process, the incoming material is separated into two or more categories based on the particle size. As a basis for design, the following characteristics are used: the desired mass flow of the incoming material, separation

capacity per screen area, and delay time of the screening. Screens can be used for the following purposes (Tchobanoglous et al. 1993):

- Removal of too big particles and pieces
- Removal of too small particles
- Sorting into light combustible and heavy incombustible fractions
- Separation of paper, plastic, and other light fractions from glass and metal
- Separation of glass, gravel, and sand from combustibles
- Separation of rocks and other large pieces from soil ingredients
- Separating big particles from ash
- Quality improvement of handled final product (for example, compost)

Various types of screening devices include trommel screens, vibrating screens (Fig. 4), and disc screens. Rotating trommel screen has been used in several applications for waste material screening and can be used as a primary screening or final screening method. The material is tumbling in the trommel until it finds a suitable opening on the screen or it comes from the other end of the trommel. The sizes of the openings in the trommel, rotating speed, and inclination all affect the trommel throughput and efficiency of the trommel.

Density Separation

Density separation utilizes the different densities and aerodynamic properties of the materials in the separation process based on a gas flow or liquid. Air separation is based on the idea that with a certain velocity of the air it is possible to float certain pieces. The required velocity is dependent on the density, form, and size of the particles. Air classifier is the most commonly used and simplest technology for density separation. Waste is dropped from the top of a chute while air is introduced from the bottom. The air can float certain particles but not heavy particles, which enables separating the light fraction from heavy fraction (Fig. 5). This technology is used, for example, after crushing the ELVs to separate a heavy fraction and light fraction (also called fluff). Density separation can also be based on

mixed C&D waste: a = fine underflow, b = magnetic fraction, c = energy waste with other material continuing to air classifier (© Havukainen)

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 5 Operating principle of an air classifier (left,

modified from Thorton 2019) and air classifier separating fluff after ELVs crushing (right, © Havukainen)

using liquids that have different densities to enable the sinking or floating of the materials. This requires specific kinds of liquids whose density can be changed. Sinking/floating devices

can be used, for example, for separating light metals.

A Ballistic separator is utilizing various properties of the waste, namely particle size, density,

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 6 Operating principle of a ballistic separator (left,

modified from Tinsley 2019) and Ballistor 6400 (right, © Lauri Rahikainen, Vimelco)

and rigidity (Christensen 2010). It can be used to separate heavy particles out of the light materials and can be placed, for example, after trommel screen to separate heavy and light fractions. It usually consists of a vibrating inclined deck which has openings in it to allow fluidizing air to pass through it. The deck is vibrating in downward or upward direction. The heavy fraction moves with the movement of vibrations. The light fraction is moving to the opposite direction because of the heavy reorganization of the waste on the deck as well as deck vibration and fluidizing air. A third fraction is formed from the material which is falling through the openings in the deck (Fig. 6).

Magnetic Separation

Magnetic separation is used to separate pieces of ferrous metals from the waste stream by utilizing the magnetic field. The magnetic separation can use either permanent or electrical magnets and the efficiency of the separation can be over 95%. The system usually involves an overhead magnet with belt conveyor which conveys the material. To ensure effective separation of the ferrous metals, there usually has to be size reduction before magnetic separation. In Fig. 7, the magnetic separation is situated after crushing and screening devices on top of the conveyor taking the screened material to the next treatment phase.

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 7 A magnetic separator over the conveying belt of the Keestrack mobile screen and separated magnetic fraction on the ground (© Havukainen)

Eddy Current Separation

Eddy current separation is a process where a voltage is formed to a conductive piece placed in the variable magnetic field. This voltage causes an electric current to the piece which induces an electrical field in turn that is polarized opposite to the variable magnetic field. The created opposite polarization causes a repulsive force between the magnetic field and the conductive piece (McDougall and White 2001). With this method, the conductive pieces can be removed from the other material flow. Alternating current or permanent magnets with different poles can be used to produce the variable magnetic field, Fig. 8. In addition to magnetic separation, eddy current

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 8 Principle of eddy current separation. (Modified from Magnapower Equipment Ltd. 2019)

separation is widely used. The purity and recovery degree can be even 98%.

Optical Sorting

Optical sorting is used to separate different materials from the waste by utilizing optical identification. The color of the material is often used as an optical identifier. The method can be used for relatively large particles with particle size over 20 cm when treating, for example, MSW. One application is to distinguish different color waste bags from each other, for example, when one color is used for mixed waste and another for energy waste. Optical sorting can also be used for significantly smaller particle size, for example, when separating copper from other metals. The copper parts are removed by an air blow by engineered air blowing from a gap between conveyors to the conveyor below. NIR (near-infrared) separation technologies utilize optical detection on the NIR wavelength region light (700–1200 nm), which allows for better penetration of the detection reducing the problems related to the impurities (Fig. 9). NIR technology is widely used in optical sorting because it enables the detection of plastic grades, as well as different fibers such as paper, cardboard, and wood. Optical sorting can achieve high sorting efficiencies. For

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 9 Illustration of the principle of an optical sorting technology. (Modified from EMS Turnkey Waste Recycling Solutions 2012)

example, Koyanaka and Kobayashi (2010) reported a sorting efficiency of 85% for nonferrous metals with a multivariate analysis-based optical sorting technology including 3D shape detection camera and a weight meter.

Compaction

The purpose of compaction is to reduce the volume requirement of material to facilitate efficient storing and transportation. Technologies usable for compaction include baling, cubing, pelletizing, and briquette production. Baling can be used for reducing volume requirement of material for transport or storage purposes of recovered material whereas cubing, pelletizing, or briquet production are sometimes used to produce densified refuse-derived fuel (RDF) or SRF. Increased costs of treatment are weighed against the transportation costs and for longer transportation distances the treatment can be justified. The performance of compaction is characterized by compaction ratio and volume reduction. Compaction ratio is the ratio of the initial volume and compacted volume whereas volume reduction is the ratio of reduced volume by compaction and the initial volume (Tchobanoglous et al. 1993).

The characteristics that need to be considered in the selection of compaction equipment include purposes for the densification, desired throughput of the material, moisture content, specific weight of the input material, available handling equipment before and after compaction as well as site-specific constraints such as available floor area and height of the space for the equipment. Another consideration is that the compacted bales, cubes, pellets, or briquets require some cover from rain even though some materials might endure moisture. One alternative for a cover for bales is to wrap them after compaction to protect them against moisture as illustrated in Fig. 10.

Robotic Separator

The development of industrial robots, artificial intelligence as well as material analyzing sensors have enabled the development of indirect sorting by automatic sorting lines. Indirect sorting means that sensors detect the materials and

robots can be used to extract the detected materials from a waste stream (Gundupalli et al. 2017). The robots allow the sorting to take place the whole week around the clock as opposed to manual picking. The utilized sensors can be selected based on the desired separated fractions such as laser-induced breakdown spectroscopy (LIBS), X-ray detection, NIR sensor, and visual light spectrum (VIS) sensor. LIBS and XRF can be used for detecting metals, different plastic qualities, or wood quality. Cameras and image recognition can be also used.

Applying a set of sensors can provide a wider range of materials to be detected and in combination with artificial intelligence a possibility for autonomous decision-making and learning of robots based on the analysis results, Fig. 11. The robotic sorting line can be used, for example, for detecting and extracting materials from presorted MSW, C&I waste, C&D plastics, waste packages, and scrap metal.

Separation and Treatment Lines

SRF Production

The aim of the SRF production line is to produce a more homogenous fuel and increase material recycling. The treatment line with crushing, screening, and various other separation devices provides an end product with more homogenous heating value compared to the untreated waste. The resulting smaller particle size distribution lowers the requirements for conveyors and feed devices. The treatment process enables the removal of harmful substances which results in lower emissions and cheaper flue gas treatment systems. In addition, the removal of harmful substance reduces the corrosivity and fouling in the subsequent combustion processes. Another benefit of the SRF production lines is to separate recyclable fractions of the waste streams, such as ferrous and nonferrous metals. According to Wilén (2004), the benefits of producing SRF from the waste include the possibility of utilizing the SRF in fluidized bed combustion or gasification with a possibility for higher steam values and subsequent higher power production efficiency.

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 12 Illustrative treatment line for SRF production

(MIPS massive impact protection). (Modified from Kuusinen 2016)

In the SRF treatment process, such as in Fig. 12, waste is first fed into a size reduction device to provide a smaller particle size for subsequent separation processes. Following treatment processes can include a magnetic and eddy current separation separating ferrous and nonferrous metal fractions for material recycling. A fine screen can then be used for removal of the fine fraction containing most of the organic waste, sand, and glass. This fine fraction removal can also be achieved with, for example, a trommel screen or ballistic separator. Fine fraction removal decreases the moisture content of waste since part of the moist organic fraction is removed. The resulting fine fraction contains mainly organic waste and can be directed to an anaerobic digestion or composting process, but the end product from these processes is contaminated by the impurities ending up to the fine fraction, thus requiring further removal of these impurities. After the removal of metals and fine fraction, the waste can be directed to a density separation process, for example, air classifier, whose main aim is to separate light fraction and heavy fraction. The heavy fraction contains heavy waste fractions such as stones as well as remaining glass and

organics. The resulting light fraction can be used as SRF or it can be directed to the additional size reduction process. Figure 13 depicts how the SRF production line can be compactly assembled at site.

Plastic Waste Separation

Mechanical treatment processes can be used to separate different plastic qualities from a source-separated mixed plastic waste. For example, in Finland, there is source separation of mixed plastic packaging organized according to the extended producer responsibility system. This mixed plastic packaging waste is directed to a plastic separation system that can then separate the different plastic polymers. For example, in the plastics treatment plant of Fortum Waste Solutions Ltd., the source-separated plastic packaging waste is separated into LDPE, HDPE, PP, mixed plastic fraction, as well as the fraction going for SRF production. LDPE, HDPE, and PP are granulated to be used in the plastics industry and mixed plastic is utilized in mixed plastic products such as profiles. According to Kampmann (2019), the outputs from plastic separation can include PET bottles, HDPE bottles, mixed plastics, PET,

Sustainability of Waste Management System: Treatment and Separation for Material Recovery, Fig. 13 SRF production line. (Courtesy of BMH)

HDPE, PP, or PS depending on the sorting scheme, source separation efficiency, and mechanical treatment efficiency.

Plastic waste separation can start with a ballistic separator which would separate 2D and 3D plastic waste from each other to different lines. The 3D plastic has distinguishable greater thickness compared to 2D plastics. The following separation line utilizing optical sorting with NIR technology can then be utilized to detect and subsequently separate desired plastic qualities. The 2D fraction can include, for example, films composed of LDPE and the 3D fraction plastic grades HDPE, PP, and PET. Both fractions will also include materials that can be further directed to mixed plastic fraction or to SRF production. After the separation of the plastic fractions the sorted plastic fractions can be directed to the subsequent washing system. This can include shredding, different processes for the washing, and drying process. Subsequently, the dried plastic fractions can then be directed to granulation and the ready granulates can be used in the plastics industry, Fig. 14. This kind of separation line has difficulties with separating black plastics since NIR technology is not able to detect it (Kampmann 2019). One possibility could be to install a hyperspectral camera such as Specim FX50 to detect black plastics (Specim 2019).

Summary

Material recycling is more feasible and efficient when there is source separation in place because source separation usually leads to the best quality of the separated materials. However, sometimes

source separation does not work properly (e.g., because of the low education level of people) or it is difficult to apply (e.g., because of a fixed and dense city infrastructure). Also, in the cases where source separation works well, there still exist significant amounts of recyclables in the mixed residual waste, and for reaching the challenging recycling targets, additional mechanical treatment and separation is needed. Mechanical treatment and separation are then used to improve material recovery and efficiency of energy recovery.

It is important to understand that both source separation and mechanical separation of materials are incomplete and after the separation, the residual part of waste still contains some recoverable materials and the separated recoverables contain impurities. This fact needs to be taken considered also in the evaluation of the environmental sustainability of waste treatment and separation. According to results from numerous life cycle assessment studies, it seems that the most important factors for the environmental sustainability of waste separation for recovery purposes are usually:

- The yield of recoverables (material recovery or recycling rate of the whole waste potential and avoidance of disposal of these materials)
- The replaced materials or fuels with the recovered materials (quality of the separated materials and demand for such materials and environmental impact of replaced virgin materials determine if there is a potential for reducing environmental impacts)

The strict material recycling targets in the EU necessitates that also mechanical separation is included as a tool for increasing the recycling rate. More guidelines and rules are being developed on how the different mass flows, for example, from an MBT plant are calculated into the recycling targets. This leads to a clearer overview of the current mechanical recycling rate nationally, as well as EU-wide. At the end of the day, the development of various treatment and separation technologies is going on and better performance is achieved.

Sustainability of Waste Management System: Waste Generation and Collection

Mika Horttanainen, Ivan Deviatkin and Jouni Havukainen
Department of Sustainability Science, LUT University, Lappeenranta, Finland

Description

Waste means any substance or object, which the holder discards or intends or is required to discard. Waste generation begins at the point in time when it is being discarded. After that, generation cannot be prevented or reduced. Solid waste includes, among others, municipal, agricultural, mining, industrial, commercial solid waste, construction and demolition waste, electronic waste, and sludge generated during wastewater treatment.

Solid waste is generated in all the stages of the life cycles of different products and materials. The largest volumes of waste are usually generated during mining and quarrying of raw materials, as

well as from construction and demolition activities. Municipal solid waste (MSW) is the most commonly known, very heterogeneous waste which is defined as solid waste originating from households and similar kind of waste generated in commerce, offices, public institutes, and municipal services. Generation rate of waste from different business fields is varying according the volume of the business activities and specific waste generation of producing a unit of each product. Municipal solid waste generation rate is affected mostly by the population and gross domestic product (GDP) per capita.

Waste collection systems consist of the waste collection bins on the yards of the houses or enterprises, loading of the waste to the collection vehicles, and further transportation to the waste treatment or disposal facilities. Waste can be collected as separate fractions or mixed waste straight from the households or other sources, or from regional collection points. If waste is not being collected, it is considered as littering, which should be avoided. Collection systems are commonly not working properly in developing counties.

Waste generation phase defines the amount and composition of waste that has to be treated, recovered, and disposed. Waste collection phase has good potential to separate recyclables and recoverables from disposable waste. Thus, these phases are very important for the sustainability of waste management.

Introduction

Waste management refers in the context of this entry and four other entries of this encyclopedia to the management of solid waste materials. Solid waste means all waste, rubbish, or litter collected and treated which is solid in nature even if its moisture content is high, such as sewage sludge. Solid waste includes municipal, agricultural, mining, industrial, commercial solid waste, construction and demolition waste, electronic waste, and sludge separated from different wastewater treatment processes. In the legislation of the European Union, waste is defined as following: “waste

means any substance or object, which the holder discards or intends or is required to discard” (Directive 2008/98/EC).

Waste management is widely related to different sustainability aspects. The original reasons for waste management are preventing and reducing environmental impacts and health hazards related to solid waste. Waste, especially biodegradable waste, is a good growing media for pathogens, which can then spread to humans via air, water, or food. Waste material can cause pollution to air, water, and soil, also in other forms like landfill gases, toxic leachates, toxic gases from inappropriate waste incineration and littering. Apart from direct environmental impacts, waste is also related to resource efficiency, diminishing natural resources and fossil materials, and rare-earth elements. It is also important for land use issues in the form of landfilling and illegal dumping. On the other hand, waste management is an important factor in municipal economy. In some developing countries the costs of waste management can be several tens of percent from the whole municipal costs. Socially, waste management is related, for example, to business possibilities and employment. One problematic issue of employment in waste management sector is scavengers, who collect waste having some monetary value and who sometimes are even living on the dump sites.

Solid waste generation is a key factor for the environmental impacts of waste management. Generation rate defines how much waste enters to the collection, treatment, recovery, and disposal systems, and it sets the basis for the extent of environmental impacts from each of these phases. Information on waste generation rates and its composition are vital for designing the waste management systems. Internationally, widely spread waste hierarchy (or priority order) defines prevention of waste generation as the highest priority option in waste management followed by preparing for reuse, recycling (use as material for manufacture), other recovery (e.g., energy recovery), and safe disposal, in this order (Directive 2008/98/EC). Waste generation phase determines also the composition of the waste directed to the waste management system.

Waste collection defines how a large share of the generated waste is directed to controlled and official treatment and disposal. Waste can be dumped or incinerated illegally, instead of collection with official systems, which usually leads to much worse environmental impacts than any legal waste management operations. Waste treatment and recovery and their sustainability can be affected with collection system by applying separate collection of different waste fractions.

Waste Generation

The term waste generation refers to the moment when the object or material is discarded, like defined in the EU directive on waste (2008/98/EC). This means that waste generation cannot be reduced with different waste treatments or utilization operations. It can be reduced only before the waste has been generated.

Solid Waste Generation

Solid waste generation sources can be divided into different economic activities. In the statistics of the European Union, rough categories of economic activities are: mining and quarrying, manufacturing, energy, construction and demolition, households and other economic activities. Waste generation from different economic activities depends strongly on the volume and intensity of each activity. Mining and quarrying forms often one of the largest shares of the total waste generation because the volumes needed for metal refining and construction purposes are large and the densities of the soil and rock materials are high. Construction and demolition waste makes also large share of the total waste generation in most of the countries, because the construction sites also handle great volumes of materials and large share of the waste materials are mineral waste (concrete, soil), which has high density. Manufacturing waste generation is totally dependent on the industrial structure of the country or region, its natural resources, labor price and knowledge level. Energy conversion produces mainly ashes and flue gas treatment residues,

and their amount depends on the sources of energy used for electricity and heat generation.

In the European Union (28 member countries), the total waste generation in 2016 was approximately 2500 million (metric) tonnes (Mt) including all the economic activities. This means that, on average, about 5 tonnes of waste per inhabitant. The shares of different economic activities in waste generation were the following (Eurostat, Waste statistics 2019):

- Mining and quarrying 25%
- Manufacturing 10%
- Energy 3%
- Construction and demolition 36%
- Households 8% and
- Other economic activities 16% (including waste water sludge 10%; services 4.6%; wholesale of waste and scrap 1%; and agriculture, forestry, and fishing 0.8%)

When using the waste generation statistics, it is important to understand how the statistics were formed. If the statistical system works well, there are certain rules on what shall be included to the statistics and what is to be excluded. These rules differ across countries making direct comparison of the statistics difficult in some cases. For example, in the European Union waste statistics, the rejects, which have been recycled internally at the site where waste was generated, is not included to statistics. This means that, for example, in agricultural waste, the manure used on the own fields of the farms is not included in the statistics. Manure is however commonly the largest waste fraction of agricultural waste, and it can be treated, for example, with anaerobic digestion to produce biogas and still be used as fertilizer for the fields. Manure is one of the largest waste flows for biogas production. Still it is not included in the statistics and the numbers in statistics cannot be used, for example, for estimating the biogas potential from agriculture. For example in Finland, the generated amount of manure is about 14 Mt and the amount of agricultural, forestry, and fishing waste in statistics is about 3 Mt (Luostarinen et al. 2017).

The most well-known and monitored waste material is municipal solid waste (MSW), which

is defined commonly as solid waste originating from households and similar kind of waste generated in commerce, offices, public institutes, and selected municipal services, such as schools and healthcare centers. Yet, municipal sewage sludge and construction and demolition waste are excluded from MSW. For MSW there is the most information available from all waste categories. The aspects of MSW generation are introduced here as one example category of different waste materials. MSW has been selected here because there is plenty of information available from MSW generation, and on the other hand, the data related to waste generation in other branches of economy is less available and more difficult to define so that it would be comparable with each other.

Globally the generation of MSW is estimated to be approximately 2 billion metric tonnes per year and it has been forecasted to grow to 3.4 billion tonnes per year by 2050. Final disposal represents still about 70% of the treatment of MSW globally. Most of the greenhouse gas emissions of waste management sector, about 1.6 billion tonnes or 4–5% of the global GHG emissions, originate from landfills, where the biological degradation of waste produces methane and carbon dioxide (What a Waste 2.0 2018).

MSW generation rate varies in a wide range in different countries and regions. The most important factors influencing the generation rate are population and its density and wealth (measured, e.g., with gross national income (GNI) per capita or gross domestic product (GDP) per capita). Figure 1 presents the variation of MSW generation rate per capita in relation to GDP per capita. It is clear that growing incomes increase MSW generation though the variation in different wealthy levels is large. It also has to be taken into account that the statistics of waste management are often very inaccurate. They are often rough estimates especially in such countries where infrastructure is poor and GDP per capita is low.

Several studies have been carried out to make models for forecasting of MSW generation (Daskalopoulos et al. 1998; Dyson and Chang 2005; Beigl et al. 2008; Kolekar et al. 2016). Daskalopoulos et al. (1998) has presented simple

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 1 Annual generation of municipal solid waste (MSW) per capita in different

countries having different gross domestic product (GDP) per capita (Global Waste Outlook 2015)

correlation equations for MSW generation in country level in Europe (1) and the USA (2) using GDP and population as variables:

$$\text{MSW} = 0.1292 \cdot \text{GDP}^{0.4412} \cdot \text{Population}^{0.4855} \quad (1)$$

$$\text{MSW} = 4.08413 \cdot \text{GDP}^{0.458} \cdot \text{Population}^{1.24075} \quad (2)$$

where

GDP is gross domestic product expressed in billion US dollars,

MSW is municipal solid waste generation, million tonnes per year.

Composition and Properties of Waste

Waste generation phase determines also the composition of waste. It is possible to affect the composition of treated waste materials significantly with the collection and separation systems and especially with separate collection of recyclables. Composition of industrial, construction, or mining waste can be influenced with the processes. The more effective the processes are, the less

utilizable waste material is produced. Also these business lines can use many of their own by-products in their own production before they are discarded and converted to waste.

Composition of the generated MSW is affected by consumption habits and abilities. It means that the income level of people is affecting also the composition of waste. We can see from the results of Global Waste Outlook (2015) in Fig. 2, that the share of organic waste is higher when income level of the country is lower. In the low income countries people are consuming less different products. Food waste forms higher share of all the waste, when the total amount of waste is much lower than in high income countries, and still the people have to prepare their food and eat. On the other hand, food products in high income countries are more often pre-manufactured. For that reason they don't produce as much waste at homes as the less prepared food materials. Pre-manufactured food is usually also packed more carefully, which also increases packaging waste in high income countries.

Figure 3 presents analyzed MSW compositions in example regions of different countries. Finland

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 2 Rough compositions of MSW in different income level countries (Global Waste Outlook 2015)

(South Karelia region) represents high income country. It can be seen that the contents of biowaste (organic waste) is significantly lower than in Brazil (Sao Paulo) and China (Hangzhou), which both represent higher middle income countries. The composition of Finnish waste does not however contain all the MSW materials because there is a well-operating separate collection system in the case region. Large share of biowaste has been separated at source in biowaste bins for composting purpose. Thus, it is important to understand from the used data, how and from which phase of waste management the composition has been determined.

Waste Collection

Waste collection includes (1) the waste collection bins on the yards of the houses or

enterprises, (2) loading the waste from the bins to the collection vehicles and (3) transportation of the waste to the first discharging place, which can be a waste treatment or disposal site or a transfer station before longer transportation. The last phase can be separated also from collection to belong in a separate transportation phase.

Waste collection is one of the key steps in the waste management systems both economically and environmentally. Waste collection from scattered generation places, especially households, forms the large share of the total costs of waste management. In developing countries it can form almost the whole cost of waste management if there is no other treatment than final disposal on non-sanitary landfills or unofficial dumps. In developed countries, other treatment costs are significant, but also collection costs increase when

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 3 Compositions of MSW: (a) Mixed residual MSW in South-Karelia, Finland

(Horttanainen et al. 2013), (b) Mixed MSW in Hangzhou, China (Havukainen et al. 2017), (c) Mixed MSW in Sao Paulo (Liikanen et al. 2018)

there are several different waste fractions to be collected.

It is not self-evident that all the waste is collected and directed to the official waste management system, which has legally and environmentally justified permissions for waste treatment and disposal. World Bank has done surveys on the collection rate of MSW in different parts of world and found that the collection rate can vary between 44% and 100%. In the developing countries the waste management and collection infrastructure is often inadequate. Significant part of waste is dumped illegally in street sides and rivers or incinerated in backyards (Fig. 4).

Purposes and Aims of Waste Collection

The main purpose of waste collection is to deliver waste from its generation location to appropriate treatment or disposal and in such a way to avoid harmful environmental impacts both in the location of generation and in the subsequent phases of waste management. Simultaneously, collection makes it possible to get waste materials recovered, and it also enables collection of data related to waste generation and treatment.

Waste collection phase includes short-term storage of waste in the waste bins. They should be planned so that they protect the environment and people from the possible harmful impacts of

waste. Such impacts are, for example, odors released from decomposing organic waste and noxious animals, like rodents, birds, and flies, attracted by the potential nutrition in the waste. Bins should also protect the waste material from spoiling before possible recycling and recovery purposes. Rain water for, example, can lower the quality of waste transported to energy recovery as well as increase the transportation costs.

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 4 Collection rate of waste (MSW) in different regions (North America (NA), Europe and Central Asia (ECA), Latin America and Caribbean (LAC), Middle East and North Africa (MENA), East Asia and Pacific (EAP), South Asia Region (SAR), and Sub-Saharan Africa (AFR)). (What a waste 2.0 2018)

Waste collection is an effective phase of waste management for separation of different waste materials. People have, in principle, a better ability for correct and accurate waste separation than any machines. It is possible to get better quality recoverables with well working source separation system than with mechanical separation.

Different Waste Collection Systems

The collection bins should be designed so that it is easy to recognize the correct bin for a waste fraction brought to the bin. Citizens should be informed properly about the separate collection system, its purposes and separation instructions at the collection sites and through different media. Figure 5 presents examples of separate collection bins of a regional collection point on the yard of a grocery store. Figure 6 presents source separation on the yard of a row house. It is also important to make source separation easy inside homes with different well-organized collection systems like the one presented in Fig. 7.

Waste can be collected from the source locations with different systems. Collection bins can be located on the yards (e.g., in shelters like in Fig. 6), where the collection truck enters and the bins are picked and emptied by the vehicle driver or an assisting person. In some countries, the collection bins are brought in certain days and daytimes to the street side to be emptied. In

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 5 A regional collection point of recyclables on the yard of a grocery store in

Finland. Series of collection bins, a bin for cardboard and instructions in the bin of metals

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 6 A waste collection shelter for recyclables and residual waste on the yard of a row house in Finland. Paper and organic waste (biowaste)

collection bins in one side of the shelter. Two shelters include bins for residual waste, paper, plastic packages, biowaste, cardboard, metal, and glass

Sustainability of Waste Management System: Waste Generation and Collection, Fig. 7 A sink with a waste cupboard including four buckets for different waste fractions

some regions the trash bags (different colors for different fractions) are brought to the street side to be picked from there to the waste trucks. The waste management fee is usually paid for the waste management company according to

the size, number, and frequency of emptying of different waste bins. Some modern tightly populated city districts have pneumatic collection system that transports the trash bags in a pipeline network to a collection point where the truck

empties or changes the container. This kind of a collection system can include also such source separation possibility that the user can select which waste he/she has placed to the system and according to that selection the system transports the bag into a correct container.

Waste can be collected also with regional collection points. In European countries, this system is often used for recyclables so that people can bring their source separated recyclable materials to the collection point, for example, when they go to a grocery store or to a gasoline filling station. The collection points are meant for those citizens who don't have separate bins for all the recyclables on their home yards, like often is the case with detached houses. The recyclable fractions can be left to these points without payment. The waste management cost is then often covered by extended producer responsibility system (including the waste management cost into the prize of a product). Some countries and regions are collecting some of the recyclables with the so-called comingled waste system, where several recyclable materials are collected in the same bin. These different fractions have to be such that they can easily be separated from each other mechanically with a good separation rate and purity.

Waste is collected often with changeable containers from such sources where the generation of waste is large. This kind of waste sources can be, for example, large department stores, construction sites, and factories. Different metal containers are used for different waste fractions. They can be open or covered. An empty container is left to the place when a full one is picked and transported to the treatment. The containers can be equipped with a compression system, when the waste has low bulk density like packaging waste.

When planning the waste collection system, the routes should be designed so that the driving distances are minimized and moving between the collection points would be smooth. Different computational systems are used for the optimization of the routes like geographical information system (GIS). Also geographic positioning systems (GPS) are used for follow up and documentation of the collection, and navigation systems for helping especially the new drivers of the vehicles.

It is also possible to equip at least larger waste bins with sensors, which follow the filling level of the bins and send the information (via internet) to the collection company. The information of the filling levels is then used for online route planning of the collection trucks. This kind of technology has been observed to save 30% in the number of emptying times in a pilot project in Finland (Uusio Uutiset 2013).

Waste collection systems are very diverse in different parts of the world. In the developing countries, the collection is more based on manual work compared to developed countries. Waste is often collected from densely populated city districts with small vehicles or carriages. Recyclables are collected by waste pickers door to door or from the waste bins and containers. In some countries, the private poor waste pickers are used as unofficial waste management personnel for the cities.

Sustainability Aspects in Waste Generation and Collection

Waste generation and the type of collection determine the composition of waste fractions directed to different treatments. If the waste directed to energy recovery contains a lot wet organic waste, it has deteriorating impact on the energy production and its environmental sustainability. If the heating value of waste is very low, there can be need to add higher energy content fuels (often fossil fuels like coal) to the incineration process to raise the combustion temperatures to the levels demanded in legislation (usually at least 850 °C) and needed to destroy the toxic organic compounds. Fossil fuel addition increases both greenhouse gas emissions and costs of the incineration. This kind of case and possibilities for improvements of the situation have been introduced and analyzed in Havukainen et al. (2017) for the city of Hangzhou in China. When the problem of wet MSW would be solved by mechanical preparation of refuse-derived fuel (RDF) in the case study, one consequence was generation of a wet mixed reject material from the process. It was shown in the life cycle assessment for the scenarios that a rational

treatment and utilization (like anaerobic digestion) should be implemented for the organics containing reject to prevent its landfilling and the methane emissions caused by that, and so to make the RDF using system environmentally sustainable (Havukainen et al. 2017).

Development of commercial (hypermarket) waste collection and treatment was studied in Hupponen et al. (2018). There was a source separation system already in the baseline scenario, which was the existing collection when the study was carried out. The collected fractions, their mass shares, and treatment methods were the following: cardboard (49%, recycling), biowaste (24%, anaerobic digestion), energy waste (11%, combustion and heat and power production), PE-plastics (2.4%, recycling), small shares of paper, metal and glass to recycling and mixed residual waste (13%, landfilling). The residual mixed waste contained 50% biowaste, 19% energy waste, 13% cardboard, 6% paper, and a small share of glass and metal. So it would be realistic to improve the source separation and get one third of the mixed waste mainly to biowaste and energy waste fractions. With these measures it was possible to reduce the greenhouse gas (GHG) emissions of the system by 5%. The most effective realistic measure for GHG emission reduction was directing the mixed residual waste to energy recovery (heat and power production with annual total efficiency of 63%), which reduced the net emissions of GHG by 93% from the baseline situation. This study, with many others concentrating on waste materials containing mainly packaging waste, shows that collection and transportation of the waste do not form significant proportion of the GHG emissions of the total waste management system (Hupponen et al. 2018).

Summary

Waste is defined as any substance or object, which the holder discards or intends or is required to discard. Waste can be generated in every phase of the life cycle of the products, materials, and services. Even the waste treatment, separation,

recycling, and recovery processes often produce secondary waste.

Waste generation rate can be affected before the waste is generated (substance or material is discarded). The rate of generation is affected by the complicity of the refining and manufacturing phases in the waste materials of different business lines. MSW generation increases with increase of population and wealth. Waste generation defines both the amount and composition of waste materials. Production processes and consumption should be developed to reduce generation of waste and to improve sustainable recycling and recovery of the waste, which cannot be prevented.

The statistics and other data, concerning waste generation, are often rather inaccurate and sometimes even unreliable. Data quality usually improves with the technical level of waste management; but in the well-developed countries where waste is mostly treated according to high standard legislation, there are significant deficiencies in the accuracy of waste generation data.

Waste collection phase of waste management secures the directing of waste materials to correct treatment and reduces environmental impacts of waste storing and spreading in the surroundings of the waste sources. From sustainability point of view, it is most important that all the waste is collected systematically by stakeholders who obey the legislation. Most of the litter in the nature, including the plastic marine litter, originates from such cities where the waste collection system does not work properly.

Separate collection of different waste fractions makes it possible to receive good quality material for recycling and recovery purposes, if the people are aware and motivated to source separation. It is however important to understand in the planning of waste management system that it is unrealistic to expect even nearly all recoverables to be placed in the correct separate collection bins. So there is usually always some residual waste containing still recoverable materials. Also, there are always some impurities in the separately collected recyclables, which have to be removed mechanically or manually and there has to be tolerance in the production processes and products utilizing the waste materials.

Sustainability of Waste Management Systems: Energy Recovery

Ivan Deviatkin, Mika Horttanainen and Jouni Havukainen
Department of Sustainability Science,
Lappeenranta-Lahti University of Technology
LUT, Lappeenranta, Finland

Synonyms

Incineration, Combustion, Energy recovery, Waste-to-energy

Definition/Description

Energy recovery from waste represents an economically, socially, and expectedly environmentally acceptable option of waste management. Energy recovery is widely represented by waste incineration, gasification, pyrolysis, and anaerobic digestion. Sustainability of all energy recovery methods is not only determined by the recovery

processes themselves but by a wide range of components of the energy recovery systems, such as waste properties, operating conditions, types of products, and demand on them, to name a few. For example, biowaste is more suitable for anaerobic digestion than incineration. At the same time, incineration of waste without the possibility to utilize heat produced neither as district, nor process heat, could have a higher impact on the environment than its gasification or pyrolysis. When systematically assessing energy recovery methods, the types of products being derived (electricity, heat, chemicals, biogas, monomers, oils, etc.), and the alternatives substituted on the market plays one of the most important roles in the sustainability of energy recovery from waste.

Introduction

Waste generation during industrial production and consumption is a fact of life. This can be compared to a metabolic waste generation by living organisms during their life-sustaining activities. As nature has gone through a long course of evolution, biological processes emerged to treat the metabolic waste and allow for the biological cycles of nutrients and other elements. On the contrary, waste generated by industrial or man-made processes and activities oftentimes cannot be treated the same way by nature and such waste requires special management provided by humans.

To enable proper handling of waste, waste management was proposed as a solution. The term “waste” is used to refer to any waste generated as a part of anthroposphere, as opposed to the waste generated during natural activities occurring without human interaction. The term “waste management” is used to refer to any activity related to management of waste from the place of its generation, or even beyond when talking about waste prevention, to its final disposal in the environment without any further interaction by humans, be it in a solid, gaseous, or liquid form. Waste management includes not only technological solutions, but also legislative, political, societal, economic, and environmental aspects as illustrated in Fig. 1.

Lately, the increasing awareness of the destructive impacts of humans on this planet led to a special emphasis on the environmental pillar of sustainability. By environmentally sustainable waste management, a system in which the consumption of virgin raw materials in any sector of the economy is minimized by reusing, recycling, or recovering valuable substances from waste, while decreasing the environmental impact is determined. Sustainability of waste management could be improved in all its aspects and should be an overarching aim of the entire waste management system and not considered for each phase of waste management independently. Such systematic thinking can be supported by using the approach of life cycle assessment (LCA).

Energy recovery from waste is an efficient measure on the path toward sustainability because it serves multiple functions. First, energy recovery allows for minimization of waste volumes ending up in landfills, which reduces the generation of landfill gas, which contains a strong greenhouse gas – methane, reduces risks of landfill fires, which release toxic emissions to the atmosphere and reduces the risks of soil and water pollution caused by landfill leachate. Second, energy recovery results in the destruction of hazardous substances contained in the waste. Third, energy recovery from waste allows for the production of heat, electricity, or fuels, which can be used to avoid generation of equivalent products from other sources, often fossil. Also, waste-to-energy is defined as a specific role toward implementation of the EU action plan for the circular economy (European Commission 2017). Therefore, energy recovery is considered a suitable measure toward providing a sustainable disposal option to various wastes, yet the factual statements can only be made based on the results of environmental, as well as social and economic impact assessments.

On the other hand, energy recovery from waste also possesses certain environmental burdens. The highest risks are related to the formation of toxic airborne emissions, as well as the generation of solid waste, such as slag, ash, and air pollution control residues, which can be toxic in nature depending on the waste being incinerated. These impacts and risks can be minimized and controlled by using advanced technologies and

Sustainability of Waste Management Systems: Energy Recovery, Fig. 1 Relation of energy recovery to sustainability through the production of heat, electricity, and fuels from various wastes under the impact of various

aspects. Social and economic aspects of sustainability are affected by energy recovery but are not included in this term of Encyclopedia

scientific know-how. However, the use of advanced technologies for air pollution control or ash management might be costly and require materials and energy inputs to their operation. Therefore, the environmental sustainability of energy recovery technologies should be analyzed.

In this entry of Encyclopedia, the sustainability aspects related to energy recovery from waste are being discussed. Environmental sustainability was given a focal point, while the economic and social pillars of sustainability were excluded from this term of Encyclopedia. Energy recovery encompasses all methods of converting waste into energy. Those methods include thermal methods, such as incineration, gasification, and

pyrolysis, biological methods, such as anaerobic digestion, fermentation, as well as chemical methods, such as esterification (World Energy Council 2016). Landfill gas recovery is also considered as an energy recovery option, yet this method is not intentionally meant for direct energy recovery from waste, rather as an option of reducing the environmental impact of waste landfilling.

Incineration

Waste incineration is a process of high-temperature (850–1450 °C) thermal treatment of

Sustainability of Waste Management Systems: Energy Recovery, Fig. 2 Key components of the waste incineration system affecting sustainability, as well as the

key components of the baseline scenario, which is assumed to be landfilling and production of substituted electricity and heat

waste, which implies full oxidation of combustibles contained in waste with air or other source of oxygen (Fig. 2). As a result of waste incineration, waste is converted into solids residues, which are collectively called ash, flue gas, and energy. Two common ways of waste incineration are known: mass-fired incineration and combustion of fuels derived from waste, also known as refuse-derived fuel (RDF) or solid recovered fuel (SRF). SRF is a type of RDF, which is certified according to the standard EN 15359 (2011). Mass-fired incineration is applied to waste generated as such without extensive pretreatment. Mass-fired incineration of MSW would most commonly be performed in grate incinerators, whereas incineration of RDF or sewage sludge would be favored in fluidized bed boilers because of higher suitability of RDF

for the process. Hazardous waste is being commonly incinerated in rotary kilns.

Each of the incineration technologies has its **benefits, drawbacks, and limitations, which affect their sustainability**. Sustainability-related aspects could be related to the waste being incinerated, to the technology used for incineration, to the possibilities for energy recovery and utilization, to the air pollution control (APC) system, to the disposal of solid waste from incineration, such as slag, ash, and APC residues, and to the operating environment. Research work of Liikanen et al. (2017) focuses on the influence of various parameters on the sustainability of waste incineration, among other waste management options. Sustainability of waste incineration depends on the composition of waste being incinerated and its

properties. The high content of water decreases the heating value of waste thus reducing the potential for energy substitution with waste, as well as affects the need for auxiliary fuels in the process. The high content of heavy metals and chlorine affect their emissions and release of polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/F). The high content of fossil carbon negatively affects climate change. Finally, variability in the composition and quality of the waste incinerated requires more flexible and efficient flue gas treatment technologies.

Grate incinerators are the most commonly applied technologies for mass-incineration of waste. In grate incineration, combustion occurs in the volume of waste on a moving metallic grate. Grates can be of different types, such as rocking, reciprocating, and traveling, among others. The grates are needed to move the waste from the feeding zone to the ash discharger while enabling its sufficient mixing with air to support combustion. Grate incinerators are suitable for highly heterogeneous waste, and thus, can be used to provide effective treatment to waste otherwise not suitable for incineration in fluidized bed incinerators. Even though the pretreatment of waste is not essential, it can be done to improve waste incineration efficiency and thus sustainability. Pretreatment might include particle size reduction and separation of recyclables, as well as wet and inert materials, yet the certain share of combustibles is also lost during the process. Considering environmental sustainability, the need for pretreatment should be determined based on the energy output of incineration, as well as the possibility to recycle materials separated, mainly metals, as compared to their separation from the bottom ash using magnetic separation for ferrous metals and eddy-current separators for nonferrous metals. On the other hand, the suitability of grate incinerators for highly heterogeneous waste possesses a serious threat on the APC systems, which are required to remove a larger variety of toxic pollutants from the flue gases.

Fluidized bed combustion (FBC) is commonly used to incinerate waste-derived fuels (RDF or SRF). Combustion of waste occurs in a

vertical cylindrical or rectangular waste incineration chamber, which is filled with fine sand particles that are kept in a fluidized form by blowing air from the bottom of the furnace. Sand particles absorb the heat from waste incineration and the heat is used to dry and heat up the moist waste supplied to the process. Because the waste incinerated is relatively homogeneous, near-complete oxidation of waste is achieved, and it is easy to control the temperatures of combustion. This also helps to control the formation of gaseous emissions, e.g., nitrogen oxides. It is also possible to add limestone to the sand bed for sulfur dioxide emissions reduction. Fluidized bed combustion requires waste to be size reduced and metals to be separated to prevent slagging of the sand bed and fouling of the heat exchangers in the boilers. Better fuel quality also makes it possible to raise the temperature and pressure of the steam generated higher than it can be achieved in grate incinerators. In this way, the electric efficiency of the process is improved. Another benefit of using RDF or SRF instead of mixed waste is a considerably smaller amount of ash generated.

Energy recovery from waste incineration and its effective utilization is the key driver toward the viability and sustainability of this waste disposal method. Energy can be recovered as both heat and electricity. While electricity can be supplied to the grid ensuring its utilization, the local demand on heat by households as district heating or by the industry as steam or thermal energy determines the possibilities for its utilization. Special attention should be given to boilers enabling efficient heat transfer, while other methods to increase energy efficiency, such as preheating of combustion air, water cooling of grates, flue gas condensation, and flue gas recirculation should be considered to increase the overall energy efficiency of incineration. The sustainability of energy recovery is also driven by the type of fuel being phased out when electricity is replaced with that from the waste incineration plant. Avoidance of fossil fuels brings substantial benefits to the process, while incineration of waste in countries where the majority of energy is derived from renewable energy sources might have little

sustainability advantages compared to other options of waste recovery and management.

The emissions from the waste incineration process are of large social, as well as environmental, concern for waste incinerators. Various APC systems have been developed and are being used in waste incinerators. Those systems often include a combination of either of the following methods: electrostatic precipitators, bag filters, cyclones, wet scrubbers, semi-wet scrubbers, active carbon injection, selective catalytic and non-catalytic reduction processes, and adsorption processes. These methods enable efficient reduction of dust, nitrogen oxides, sulfur oxides, acids, heavy metals, and chlorinated compounds. Also, process conditions might be varied to influence the emissions of nitrogen oxides, carbon monoxide, heavy metals, and PCDD/Fs. Finally, the content of chloride-based compounds, mercury, and other toxic metals in flue gases can be reduced by avoiding those elements in the feeding waste. The regulations concerning waste incineration and its emissions are strict in the EU and other developed countries. The regulations state the limits and measurement demands for a higher number of emission components than the regulations of conventional fuels combustion. In addition, there are regulations for combustion conditions to ensure the destruction of toxic organic compounds in all the process conditions.

Recovery of metals and other incombustibles from mixed waste is one aspect having a significant impact on the sustainability of waste incineration. On one hand, incombustibles contained in the mixed waste can be removed prior to waste incineration. When doing so, other waste fractions will also be lost during the mechanical pretreatment of mixed waste due to an inefficient separation of different waste fractions. This leads to a decrease in the energy input to the incineration process. Furthermore, the final disposal of rejects, fine, and heavy fractions from the RDF production should be considered since their recycling might be challenging. Removal of incombustibles from waste to produce RDF increases the incineration efficiency. On the other hand, incombustibles can be subjected to

incineration in grate incinerators. By doing so, incombustibles will end up in the bottom ash and slag, from where ferrous, nonferrous, and mineral fractions can be recovered. Therefore, systematic assessment of alternative systems for handling incombustibles in waste should be performed accounting for the separation processes themselves also for the mass and quality of metals and other noncombustibles separated and recycled. Recovery of metals is expected to preserve natural resources, which would otherwise be used to produce metals substituted with those recovered from waste.

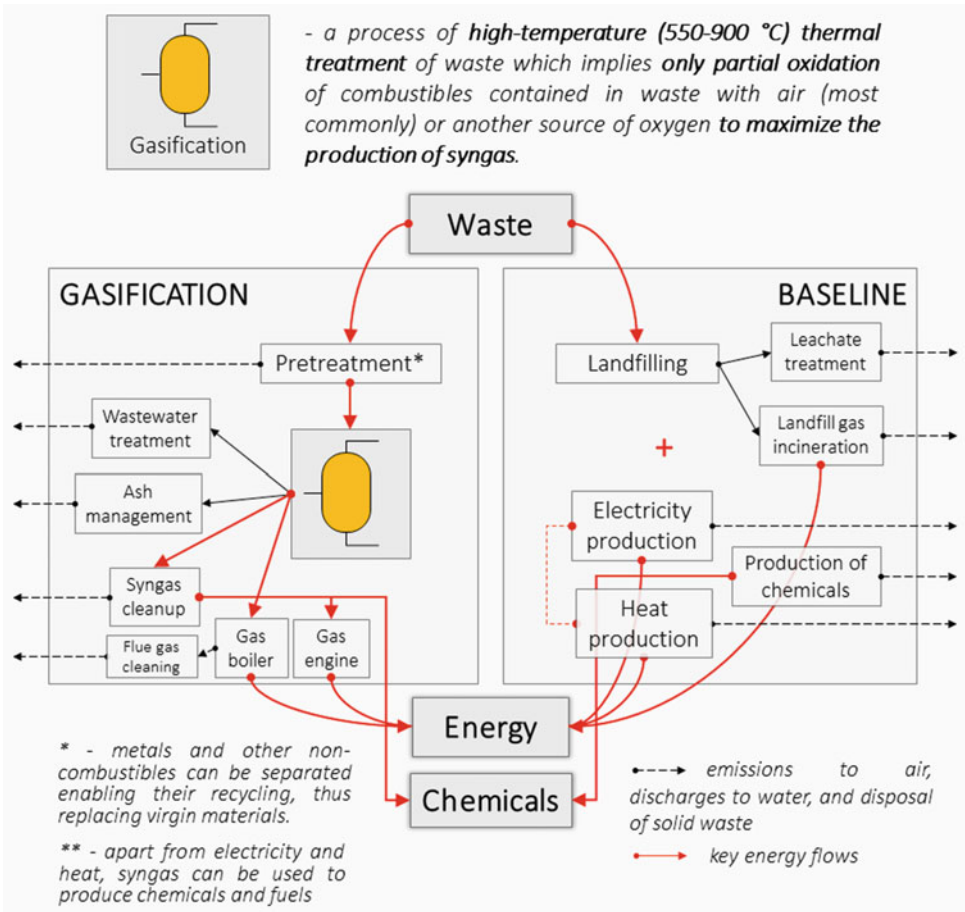

The operating environment, which includes political, legal, and geographical aspects, might be one of the most decisive aspects of the sustainability of waste incineration and other waste-to-energy technologies. The legal aspects affect sustainability in terms of the emission limits, which are getting more stringent with the development of novel APC techniques and increasing social pressure. Political aspects affect sustainability through the country- or region-specific policies on waste management, recycling, and incineration. Geographical aspects determine the availability and proximity of heat consumers, which is an important factor accounting for the high losses of thermal energy during its delivery to the point of utilization. Electricity transmission has a lower dependency on the local market since it can be supplied to the grid and utilized. Finally, when the sustainability of waste incineration is assessed, the potential reduction of the environmental impact is calculated through the avoided electricity and heat production, which would otherwise occur without waste incineration. Oftentimes, marginal electricity and heat sources are accounted for, and not grid mixes. Determination of a marginal electricity or heat source is done through analysis of historical data for a specific area on the generation of electricity and heat. When the electricity grid is carbon-intensive and the efficiency of energy recovery from waste is high, energy recovery from solid waste can have higher benefits than material recycling from the climate change point of view. See Subsection "MSW management in Sao Paulo, Brazil" of this entry.

More detailed discussion on the sustainability of waste incineration as well as any other energy recovery methods, includes consideration of various aspects. One of the aspects is the type of electricity and heat displaced on the market, i.e., the so-called consequential vs. attributional approaches. Another aspect is the use of the zero-burden approach considering that waste carries no burden from the preceding life cycle stages. With the increasing trend of the circular economy, waste should rather be considered as a resource, thus carrying certain debit from the previous life cycle stages. Consideration of the baseline scenario also has significant impacts on the results. For example, landfilling of organic waste is banned in some European countries making

landfilling only a hypothetical option. More considerations on the LCA of waste management can be found in another entry of this Encyclopedia (see entry ► [“Sustainability of Waste Management System: Environmental Impact Management with Life Cycle Assessment”](#)).

Gasification

Waste gasification is a process of high-temperature (550–900 °C) thermal treatment of waste, which implies only partial oxidation of combustibles contained in waste with air or other source of oxygen (Fig. 3). As a result of waste gasification, waste is converted into fuel gas,

Sustainability of Waste Management Systems: Energy Recovery, Fig. 3 Key components of the waste gasification system affecting sustainability, as well as the

key components of the baseline scenario, which is assumed to be landfilling and production of substituted electricity, heat, chemicals, and fuels

which is also referred to as syngas or producer gas, and ash. Syngas mainly consists of carbon dioxide, hydrogen, carbon monoxide, and methane, while the presence of particulates, tars, acids, and other impurities is possible. Unlike waste incineration, waste gasification is performed to only partially oxidize waste, which is required to generate enough heat for the self-supporting gasification process. Air is usually supplied at 20–30% of the stoichiometric need. Arena (2012) elaborates on waste gasification in more details.

As with waste incineration, there are several factors that affect the sustainability of waste gasification. Waste should be rather uniform and preferably have a particle size of below 100 mm. Therefore, the quality and composition of waste determine their applicability for the process as such. Oftentimes, waste needs to be size-reduced and noncombustibles be removed prior to gasification. The gasification process is energetically self-sufficient meaning that no external energy is needed for the process. Furthermore, no specific and dedicated air pollution control system is needed since the fuel gas could be sent to further clean-up to remove acidic compounds, tars, particles, and other impurities. Air pollution control is, however, needed after the combustion of fuel gas, yet the requirements for its incineration could be lower than during incineration provided that producer gas has been cleaned up properly.

There are certain benefits of waste gasification over incineration. Firstly, higher energy efficiencies could be achieved when fuel gas is combusted in gas boilers, which have higher efficiencies when compared to conventional waste incineration boilers. Secondly, the fuel gas is an intermediate product, which can be stored, transported, and utilized in places with the highest demand, thus enabling the substitution of fossil fuels. This is an advantage since the substitution of electricity and heat during waste incineration might not always result in avoided environmental impact.

Gasification can be used also for co-combustion purposes. Waste can be gasified and the fuel gas can be combusted in an existing

plant burning conventional fossil fuels. With the fuel gas from waste, it is possible to replace fossil fuels without changing the whole process and without supplying solid waste to the conventional furnace.

Pyrolysis

Waste pyrolysis is a process of high-temperature (typically around 400–700 °C) thermal treatment of waste, which implies heating of combustibles contained in waste in an oxygen-free environment (Fig. 4). As a result of waste pyrolysis, waste is converted into organic liquid products, such as oils and waxes, which are condensed from produced gas, non-condensable flammable gases, and char. The pyrolysis conditions can be adjusted to maximize the yield of a specific component. Pyrolysis has been mostly practiced to dispose of tires, plastic, or dried sewage sludge. Pyrolysis gained less attention in the treatment of MSW due to its high moisture content, high heterogeneity, and large particle size, yet some experimental research has been performed. Chen et al. (2014) elaborate on MSW pyrolysis in detail. Martínez et al. (2013) and Williams (2013) explain the pyrolysis of tires. Inguanzo et al. (2002) discuss the pyrolysis of sewage sludge, while Anuar Sharuddin et al. (2016) explains the pyrolysis of plastic waste.

Sustainability of waste pyrolysis strongly depends on the quality of waste feedstock, which is explained by the need for waste drying and size reduction (Fig. 4). Integration of the pyrolysis unit to a combined heat and power plant to incinerate non-condensable gases and char to generate energy, which can be supplied to the pyrolysis process itself, as well as on the local market, is a feasible option to improve the sustainability of the process. The majority of the environmental impact does not occur in the pyrolysis unit itself, but elsewhere in the value chain, i.e., during incineration of gases, char, and organic liquid products. Organic liquid products could be further refined to produce fuel and/or chemicals. Therefore, the yield of the organic products, which might be affected by using catalysts, the need for their

Sustainability of Waste Management Systems: Energy Recovery, Fig. 4 Key components of the waste pyrolysis system affecting sustainability, as well as the key components of the operating environment expressed

through the baseline scenario, which is assumed to be landfilling and production of substituted electricity, heat, fuels, and chemicals

upgrading, and the fuels being replaced strongly affect the sustainability of the process.

Anaerobic Digestion

Anaerobic digestion is a process of low-temperature (37 °C for a mesophilic process and 55–70 °C for a thermophilic process) biological treatment of organic waste, which implies degradation and stabilization of organics contained in waste under anaerobic conditions (Fig. 5). As a result of anaerobic digestion, organic waste is converted into biogas and microbial biomass, i.e., digestate. Anaerobic digestion

has been applied, e.g., to the treatment of sewage sludge, biowaste, and agricultural waste. Commonly, anaerobic digestion is applied to moist waste consisting of quickly biodegradable organic matter, which is separated from other solid waste.

Sustainability of anaerobic digestion is determined by many factors, including the energy need for the process, the moisture content of the feedstock, need for feedstock collection and transportation, among others. Berglund and Börjesson (2006) showed that the energy input to biogas production corresponds to some 25–40% of the energy output in biogas produced, but the variation is high depending on heating needs due to varying climate conditions, the yield of biogas,

Sustainability of Waste Management Systems: Energy Recovery, Fig. 5 Key components of the waste anaerobic digestion system affecting sustainability, as well

as the key components of the operating environment expressed through the baseline scenario

and the level of automation. Most of the energy input is for the heating and electricity supply to the anaerobic digestion process. Application of digestate on land might result in reduced eutrophication and global warming potentials when compared with the use of mineral fertilizers produced using energy incentive Haber-Bosch process. Finally, the upgrade of the biogas is an important step toward sustainability since this biogas can be utilized as a transport fuel, thus replacing natural gas or gasoline.

Examples

MSW Management in São Paulo, Brazil

Incineration of MSW with energy recovery in Brazil might have a higher impact on global

warming potential (GWP), also referred to as climate change, acidification potential, and eutrophication potential when compared with MSW landfilling equipped with landfill gas recovery and generation of electricity from Brazilian electricity mix (Liikanen et al. 2018). A higher impact from incineration compared to the reference situation was, first, due to an assumption for a high collection rate of landfill gas (64% or 80% depending on the landfill), and second, due to low environmental impact from the Brazilian electricity grid mix (75% of electricity generated is from hydropower). However, when the landfill gas collection rate was decreased to 50%, MSW incineration was more favorable. Similarly, when the type of electricity substituted was changed to natural gas or heavy fuel oil, incineration was more favorable when compared to landfilling.

Overall, the production of RDF from MSW and its combustion in a cement kiln to replace coal, as well as anaerobic digestion of an organic fraction was the best scenario in the study.

MSW Management in Hangzhou, China

The MSW management in China could be improved by the production of RDF and efficient recovery of the organic rejects generated therein as highlighted by Havukainen et al. (2017). Production of RDF led to increased efficiency of energy recovery during waste incineration and avoidance of the use of coal as auxiliary fuel to raise the combustion temperatures to the level demanded by legislation and dioxin reduction. However, landfilling of organic rejects could diminish these benefits, so its proper management, e.g., by anaerobic digestion, should be practiced. Significant potential toward sustainability of energy recovery from MSW lies in improved source-separation of biowaste and, thus increased energy recovery efficiencies and avoided consumption of auxiliary fuel during waste incineration, which is currently coal.

MSW Management in South Karelia, Finland

Incineration of MSW in the region of South Karelia, Finland, helps to mitigate climate change, yet not under all operating environments as studied by Hupponen et al. (2015). Mitigation of climate change was possible due to avoided emissions from landfilling, as well as avoided emissions from electricity and heat substitution in the waste incineration plants. However, when the heat substituted was mainly derived from biofuels (72%), the reduction of the impact on climate change was significantly lower compared to the cases where heat replaced was derived from natural gas. When comparing different incineration solutions, it is important to take into account the annual efficiency of energy production instead of technical efficiency. For heat recovery, seasonality of heat demand is an important aspect since district heating of buildings is only required during winter time, whereas steam can be utilized in the industry all year round, which increases the total annual efficiency of industrial heat recovery significantly. Effective heat recovery, in general, represents a

very important possibility to improve the environmental sustainability of waste-to-energy, which can be seen when comparing the results of waste-to-energy studies done for countries in cold climate and warm climate regions. It is important to realize that industrial needs for heat exist also in warmer climate zones and this possibility should be utilized more effectively in waste-to-energy.

Commercial Waste Management in Finland

Energy recovery from mixed waste and energy waste had the largest global warming reduction potential out of several waste fractions as studied by Hupponen et al. (2018). Apart from incineration, recycling of biowaste, cardboard, polyethylene, paper, metals, and glass was studied. Despite the fact that waste incineration releases substantial amounts of greenhouse gases, large benefits for mitigation of climate change are achieved through substitution of energy, which was derived from hard coal, natural gas, peat, or a Finnish electricity grid mix. While incineration and recycling of all waste fractions resulted in a reduced impact on climate change, recycling of cardboard proved to have higher impacts than the production of cardboard from virgin raw materials. This might be related to the low impact from virgin cardboard production in pulp and paper mill integrates where energy is supplied via combustion of wood and other bio-based residues.

Ash Recycling in Finland

Proper management of thermal residues, which is a collective term used to refer to bottom ash, boiler slag, fly ash, and air pollution control residues, affects the entire sustainability of waste incineration; yet, the impact from thermal residues management has a relatively low impact compared to waste incineration itself. Recycling of bottom ash, boiler slag, and fly ash from incineration of various fuels, including municipal solid waste was studied by Deviatkin et al. (2017a). The studied recycling options included forest fertilization, landfill construction, road construction, and road stabilization, depending on legal and technical acceptability of different types of thermal residues and fuels used in incineration. Each of the studied recycling methods had a reduced impact

compared to landfilling across several impact categories, such as global warming potential, ozone layer depletion potential, acidification potential, and eutrophication potential. In some cases, substitution of products manufactured from virgin materials resulted in large avoided impact on climate change, such as substitution of cement, whereas avoided phosphorous fertilizer production led to significant reduction of abiotic resource depletion potential. The impact of ash recycling on toxicity-related impact categories varied significantly from avoided impact to induced one depending on a specific scenario. In most of the cases, leaching from thermal residues was determined by the liquid-to-soil ratio, which was modeled based on precipitation in a specific area, depth of ash disposal, the density of materials, among other parameters.

However, ash recycling might also cause additional impacts on the environment as studied in another paper of Deviatkin et al. (2017b). Advanced treatment of bottom ash allowing efficient separation of ferrous metals, nonferrous metals, and minerals of four different fractions with consequent utilization of only limited amount of the minerals in the production of cementitious products has a slightly larger non-toxic environmental impact when compared with the production of similar products from conventional materials. This was due to induced environmental impact during pretreatment of bottom ash, as well as additional consumption of cement during the production process when minerals obtained from ash were utilized. The situation would change if more minerals were utilized. Moreover, if the impact of the recycling of non-ferrous and ferrous metals were included, the results can be expected to have a lower environmental impact.

Comparison of Waste Incineration Versus Gasification

In the study by Arena et al. (2015), incineration of residual MSW in a moving grate combustor was compared with its gasification in a vertical shaft gasifier. The results indicated that waste incineration has lower emissions than gasification across

many impact categories, including the impact on climate change. The higher impact from gasification was due to the use of metallurgical coke in the process to enable high temperatures in the molten section of the gasifier.

Pyrolysis of Waste Plastics

In the study by Perugini et al. (2005), pyrolysis of waste plastics had a lower impact on climate change compared to its incineration or landfilling. Mechanical recycling of polyethylene and low-temperature pyrolysis of polyolefins released 4.2 times fewer greenhouse gases than incineration with energy recovery and 3.1 times less compared to landfilling. The largest avoided impact originated from avoided production of polyethylene and polypropylene.

Nitrogen Recovery from Sewage Sludge

Sustainability of energy recovery from sewage sludge during its digestion or incineration might be further reduced by seizing the potential of nitrogen recovery during its drying (Deviatkin 2017). A reduction of the impact on climate change of 30% could be achieved when nitrogen is recovered during thermal drying of sewage sludge when compared to its incineration without nitrogen recovery and production of nitrogen fertilizers via an energy-intensive Haber-Bosch process.

Summary

Energy recovery from various waste streams might represent sustainable waste management options. Despite the significant emissions originating either directly during the waste-to-energy processes, e.g., incineration, or during incineration of products obtained therein, such as syngas, pyrolysis oil, or biogas, energy recovery from waste usually contributes to the reduction of environmental impact through avoided conventional disposal of waste, which is oftentimes landfilling in developing countries or in countries with economies in transition, and due to expected avoided production of electricity, heat, fuels, and chemicals, which could be produced from waste.

Availability and composition of waste strongly affect the sustainability of energy recovery from waste. Furthermore, sustainability of energy recovery is determined by the right choice of the treatment method, e.g., anaerobic digestion of biowaste versus its incineration, or pyrolysis of plastic waste versus its incineration in countries with the low carbon intensity of electricity grid mixes. Finally, the operating environment determines the sustainability of the energy recovery options within a range of other waste management methods. Therefore, attention should be given not only to the energy recovery methods but also to the environmental impact of the conventional disposal methods of specific waste and to the types of replaced products.

Disposal; Landfilling

Definition/Description

Waste disposal onto land is a historically common way of handling our waste. In modern society, however, waste disposal in an uncontrolled manner, i.e., its open dumping and littering, is considered illegal in most parts of the world. Yet, open dumping is still the most common waste disposal method worldwide covering 33% of municipal solid waste (MWS) generated. Waste is mostly being dumped in low-income countries, which lack infrastructure and financial instruments for efficient transition toward environmentally

sustainable waste management systems. Compared to dumping, sanitary landfilling (covers 8% of MSW generated globally) introduces a range of measures to surpass the negative impacts on the environment, which include leachate and landfill gas collection and treatment. Nevertheless, landfilling is the least desired waste management method in developed countries, which is due to the loss of economic benefits embodied in waste and the depressing impacts on the environment during landfilling. This entry of the Encyclopedia focuses on the environmental impacts of the final disposal of waste and its impacts on human health and natural environment.

Introduction

The beginning of the twentieth century can unconditionally be marked as an era of waste management. After decades of tightening legislation, first, on air pollution control and then on the protection of water bodies, environmentally safe treatment and disposal of waste have been a focal point for policymakers and companies across many nations. There has been a firm move toward promoting material recycling and even closure of the material loops. Such moves were the strongest in developed countries. This has been made possible through sustainable waste management, which has gained momentum due to a profound understanding of the negative impacts caused by waste landfilling, or even by illegal open dumping of waste.

Nevertheless, even after making significant efforts toward closing the material loops, waste landfilling and dumping remain the dominating waste management methods globally. As of 2016, landfilling and open dumping accounted for disposal of 70% of all municipal solid waste (MSW) generated (Fig. 1) (Kaza et al. 2018). Furthermore, the Circularity gap report (Circle Economy 2019) calculates that only 9% of extracted resources make their way back to the production processes. For this reason, analysis of the final disposal methods and their relation to sustainability is essential, even if being seen obsolete in the developed world.

Sustainability of Waste Management Systems: Final Disposal, Fig. 1 Shares of MSW treatment and disposal methods globally (Kaza et al. 2018)

Definitions of final disposal in regulations of different countries vary. According to the European Directive on Waste (The European Parliament and the Council of the EU 2008), disposal means “any operation which is not recovery even where the operation has as a secondary consequence the reclamation of substances or energy.” The disposal methods include, among many other methods, deposit into or on to land, deep injection, specially engineered landfill, and incineration on land and sea. According to the Resource Conservation and Recovery Act (USEPA 2019), disposal means “the discharge, deposit, injection, dumping, spilling, leaking, or placing of any solid waste or hazardous waste into or on any land or water so that such solid waste or hazardous waste or any constituent thereof may enter the environment or be emitted into the air or discharged into any waters, including ground waters.” According to the Australian EPA (2019), disposal is a “final stage in the management of waste, which includes treatment of waste prior to disposal, incineration of waste, with or without energy recovery, deposit of waste on land or water, discharge of liquid waste to sewer, permanent indefinite or long-term storage of waste.” For the purpose of this entry, the definition of disposal provided in the EU Directive on Waste has been followed.

Final disposal is the least desired method of waste handling according to the waste hierarchy,

which has been widely adopted in waste management legislation across the world (Fig. 2). The key reason for avoiding final disposal, apart from the negative impacts on the environment, is the loss of materials, which enter the society via consumption of various products during their disposal, thereby generating the need for extraction of an equivalent amount of raw materials or even more accounting for the ecological rucksacks of products.

Final disposal can be avoided by a range of methods. At first, generation of waste as such could be prevented through reduced and responsible consumption, which however requires societal transition. Measures toward dematerialization of production processes, digitalization, extension of products lifetimes, and promotion of the product-as-a-service business models could help to reduce the amounts of waste. Once waste is generated, its final disposal can be prevented through its reuse, redistribution, remanufacturing, recycling, or recovery. Yet, these waste management options require technological know-how and creation of favorable operating environments, including economic, political, and legislative drivers.

This entry focuses on the most common final disposal method practiced worldwide, namely, landfilling, open dumping, and open burning. It will mainly focus on the environmental impacts of the final disposal of MSW. What relates to the economic dimension of sustainability, final disposal of waste results in the loss of economic value contained in waste, which otherwise could be recycled for the manufacturing of new materials and products. Regarding the social counterpart, final disposal of waste poses high risks of negative impacts on human health and natural capital, as well as creates visual nuisances if located in populated areas.

Landfilling

According to the estimates of the current state of the global waste management systems, which naturally include a large body on uncertainty, 4% of all waste globally is disposed of in controlled landfills, 7.7% of waste is sent to sanitary landfills

Sustainability of Waste Management Systems: Final Disposal, Fig. 3 Key mechanisms of environmental protection during waste landfilling

Protection of Soil and Water

The main source of possible impact from landfills on soil and water is due to land occupation and leachate formation. Leachate is a liquid generated during penetration of precipitation through the waste landfilled, as well as free water contained in the waste landfilled, especially contained in biowaste. As a result of contact with waste, leachate is enriched in organic matter, which is determined by the biological and chemical oxygen demands, suspended solids, a wide range of macrocomponents, such as phosphorus, chloride, sulfate, and a spectrum of heavy metals including chromium, cobalt, and lead (Kjeldsen et al. 2002; Renou et al. 2008).

To prevent the penetration of leachate into soil and groundwater, landfills are equipped with bottom liners as well as leachate collection and treatment systems. A bottom liner is a structure consisting of several layers, whose thickness and materials are determined by the type of the landfill (for inert waste, for nonhazardous waste, or for hazardous waste). In general, the bottom liner consists of a layer of aligned subsoil, geosynthetic clay liner, geomembrane, and a drainage layer (Fig. 4).

The drainage layer contains coarse materials, such as gravel to ensure free flow of leachate. Under the drainage layer, there should be a

Sustainability of Waste Management Systems: Final Disposal, Fig. 4 A typical structure of the bottom liner of a landfill

synthetic or natural barrier to prevent water penetration to the soil effectively. Above the drainage layer, there should be a layer of material (e.g., geotextile) which prevents particulate matter and organics to penetrate into the drainage layer and to fill the pores there. The bottom liner is usually characterized by its permeability to ensure slow penetration of liquids through the liner. However, the bottom liner is not sufficient without a leachate collection system, which is required to withdraw the leachate formed from the bottom of the landfill. The leachate collection system is essentially a network of pipes placed in the drainage layer of the bottom liner connected with the collection pump, a pond, and with an off-site wastewater treatment plant, if needed. After a landfill closure, the amount of leachate formed is significantly reduced by construction of a landfill top cover. Nevertheless, the European Directive on Landfill of Waste demands that landfills are taken care of for the period of at least 30 years after their closure, which also includes leachate collection and treatment.

Landfill Gas Control

Food and green waste comprise a significant portion of MSW globally – approximately 44% according to Kaza et al. (2018). The lowest share of biowaste in MSW in the EU is recorded in Lithuania, Norway, and Slovenia being less than 20% (EEA 2013). The share of bio-based waste is

expected to be lower in high-income countries. However, recent research done in Finland showed that the content of biowaste was 48.4% and 42.9% in two case studies performed (Liikanen et al. 2016). Furthermore, the share of biowaste is above 50% in Greece, Portugal, Slovakia, and Malta (EEA 2013). The share of biowaste is even higher in China being reported at the level of 55.8% (Zhou et al. 2014). It is worth mentioning that methodologies on reporting waste generation might vary between countries.

Accounting for the high share of biowaste in MSW, it is expected that substantial amounts of biogas are formed during waste landfilling. Biogas, which is more specifically referred to as landfill gas, is a gas formed during microbial degradation of landfilled waste under anaerobic conditions. Landfilling of 1 t of MSW generates approximately 100–300 m³ of landfill gas, which is roughly comprised, in equal proportions, of methane and carbon dioxide (Themelis and Ulloa 2007). Both gases are greenhouse gases making landfill gas a serious threat to climate change. However, carbon dioxide is often considered climate neutral since it is formed during the degradation of biogenic matter of waste and is a part of the natural carbon cycle. On the other hand, methane is considered to contribute to climate change since it cannot be directly sequestered by biomass via photosynthesis and thus remains in the atmosphere for a certain time.

To reduce the negative impacts of landfills caused by the release of the landfill gas, landfill top covers as well as landfill gas collection and treatment systems are being employed (Fig. 5). The top cover usually consists of several layers, which include a precover or a foundation layer, a gas collection layer of gravel, a sealing or a hydraulic layer of clay, a drainage layer of gravel, a protection layer, and a surface layer of soil for vegetation growth. The top cover minimizes rainfall penetration, as well as prevents the escape of the landfill gas and enables partial oxidation of methane. In the porous drainage layer, the rain and melting water penetrating through the surface layer flows easily with the help of gravitation toward the surface water collection system.

Sustainability of Waste Management Systems: Final Disposal, Fig. 5 A typical structure of the top cover of a landfill

Sealing layer minimizes the water flowing downward and landfill gas flowing upward. Gas collection layer also consists of a porous material where the landfill gas flows easily toward the perforated gas collection pipes, which have under pressure conditions. The landfill gas collection system is also a network of horizontal pipes and vertical dwells connected with gas pumps and with a flaring plant or an energy recovery unit. Landfill gas generation is often described with a first-order decay model described by the following equation:

$$Q_g = \sum_{i=1}^n \sum_{j=0.1}^1 k \left(\frac{M_i}{10} \right) L_{0i} e^{-kt_{ij}}$$

where i, j are the indices, n is duration of waste acceptance in landfill (yr), k is first-order decay rate constant (yr⁻¹), M_i is the tonnage of waste disposed in year i (Mg), L_{0i} is methane generation potential of waste disposed in year i (m³ Mg⁻¹), and t_{ij} is the age of j th section of waste M_i (yr) (Amini et al. 2013). The landfill gas generation decreases steadily during the aftercare period. When landfill gas is incinerated, methane is oxidized to carbon dioxide, thus reducing the impacts on climate change. Similar to the leachate collection, landfill gas collection should be in place for at least 30 years after the landfill closure to

minimize its impacts on the environment. With this time frame, most of the landfill gas is expected to be generated and possibly collected, thus minimizing the environmental impacts.

Emissions of methane can be estimated using the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2006). There are various parameters that affect the generation of methane, a key greenhouse gas generated during landfilling. Those parameters include the composition of waste, the share of degradable organic carbon (DOC), which varies across waste fractions and is the highest for wood and straw – 0.43 and is only 0.15 for food waste. However, not all DOC decomposes into landfill gas, so the fraction of DOC, which dissimilates, DOC_f , is introduced and equals to 0.1 for wood and 0.7 for food waste thus indicating the higher degradation of organics contained in food waste. The model accounts for the methane generation rate, the fraction of methane in landfill gas, oxidation factor, and carbon storage in paper and wood. Also, the model accounts for the different types of landfill structures through a methane correction factor (MCF). It is worth mentioning that the majority of those parameters have a wide range and thus the results could be only indicative if no primary data from the landfill was obtained. Furthermore, field measurements of the landfill gas generation are challenging, thus leading to a wide use of default values and models. Kaza et al. (2018) estimated that 2.01 billion tons of MSW was generated in 2016, while waste management sector is responsible for the emissions of 1.6 billion tons of carbon dioxide equivalents, which includes, but not limited to, final disposal of waste.

Deficiencies of Landfill Protection Systems

Despite the high emphasis on the development and implementation of landfill protection systems, there are certain factors that affect their impacts on the environment. One of the major environmental concerns of landfill is the formation and release of landfill gas. At first, landfill gas collection systems are not generally installed in actively used landfills, thus resulting in the release of LFG during its

active phase. When the LFG collection system is installed, the collection of gas begins. However, not all LFG is collected from landfills. One reason for inefficient collection is the breakage of the sealing system resulting in the release of LFG into the atmosphere. Another reason is blockage of the piping systems with water, waste, or landfill cover materials preventing efficient collection of the gas. The LFG collection rates vary significantly between 20% and 90%, yet the higher range is challenging to achieve. Finally, a part of LFG, yet insignificant, is formed after the end of the aftercare period, thus being released to the environment.

When considering the bottom liners, another set of deficiencies arise. First, the bottom structures can crack due to soil movement, thus resulting in the release of leachate into soil and possibly further to groundwater. Also, the leachate collection system can be blocked with physical objects preventing the removal of leachate from the bottom of the landfill, thus resulting in leachate accumulation increasing the risks of its penetration to the natural environment. The release of leachate poses risks of toxic impacts on the natural environment.

Finally, the large source of acute impacts of landfill is due to landfill fires. Landfill fires are generally occasional events occurring due to high content of oxygen causing increased biological activity and thus causing spontaneous self-ignition of waste. When fires spread deeper, they cause deep seated fires, which are challenging to extinguish. Landfill fires are a source of a wide range of compounds including dioxins and furans released to the atmosphere without any control possibility thus affecting neighboring communities.

Other Disposal Methods

Open Dumping

Open dumping of waste is a long-standing way of handling the waste generated by households or during industrial production. In the past, the population was scarcer, materials were often

bio-based, and no knowledge on the negative impact of waste disposal on human health or environment existed. Nowadays, the situation is controversial: population growth follows an exponential trend, especially in developing countries or countries with economies in transition yet the population growth peaked in the 1970s, materials are complex and are often fossil-based. Also, a significant body of research has been collected on the health impacts of substances released to water through leachate and to air through occasional fires during open dumping of waste (WHO 2015).

Open dumping is essentially an uncontrolled placement of waste in any locations where waste starts to be accumulating making it a commonly accepted place among citizens and law-breaching companies. Oftentimes, open dumping is considered an illegal waste disposal method even in developing countries. But due to lack of legislative mechanisms and being a commonly accepted practice, it is still a common practice in many places. Also, the difference between open dumping and official landfilling is faint because many of the official landfills in developing countries are just accepted by authorities but are not constructed according to any environment protection practices. According to the report prepared for the World Bank (Kaza et al. 2018), 93% of MSW is still dumped in low-income countries with the share being 66% for the lower-middle income countries, 30% for the upper-middle income countries, and only 2% for the high-income countries. The increasing prosperity of people living in developing countries in the future is expected to reduce the share of waste being dumped with an increasing share of landfilling or even introduction of waste recycling systems.

There are various mechanisms of the negative impact of open dumps on the environment (Fig. 6). Firstly, open dumps affect wildlife due to waste being physically present in the natural environment, which is also referred to as littering. Secondly, open dumping of waste leads to accumulation of waste on the ground preventing normal vegetation as well as pollution of soils through leachate. Thirdly, open dumping

Sustainability of Waste Management Systems: Final Disposal, Fig. 6 Impacts of open dumping on the environment and human health

deteriorates groundwater and in turn affects people whose water is supplied from the polluted water sources as well as sea life through flushing of waste from dumps located close to rivers or on seashores. Also, open dumping of waste leads to air pollution through the release of particles, creation of offensive odor in the vicinity, and through the formation of toxic substances during uncontrolled and occasional fires. All of these negative impacts are also probable in controlled and sanitary landfills, but they are much more common and happen more often and with larger impacts in the open dumping, which do not have any protective structures or practices to prevent the environmental impacts.

Presence of waste in the natural environment affects wildlife. Animals and other living organisms see open dumps as places of easily available food. Therefore, open dumps attract wild animals as well as domestic livestock. Eating food waste, which might contain toxic substances and pathogens, by livestock might result in their accumulation in the food chain and a consequent transfer to human bodies. Animals are also under risk of suffocation by accidental intake of large waste items. Another risk of open dumps is due to spreading of diseases by rodents populating the dumps.

The most significant impacts of open dumps on the environment and human health are, however, those originating from soil degradation, pollution of water bodies, and from the release of airborne emissions. Dumping of waste occupies significant land territories and leads to their pollution through leaching of organic and inorganic pollutants, as well as toxic substances during atmospheric precipitation. Leached substances are then transferred to the underlying soil and are being partly accumulated therein or transferred further to groundwater. Rain and stormwater also leach organics and hazardous substances from waste to the surface waters and even flush waste to the rivers, lakes, and seas. In some regions of developing countries, dumps are still established on the riversides. During flooding seasons, the waste goes with water and ends up in seas and oceans resulting in ocean littering and plastics. Surface water pollution affects fish and other seafood and spoils drinking water in many cities.

Deliberate or unintentional burning of open dumps releases a wide range of pollutants to the atmosphere. The emissions of the highest concern to the human health are those from the incineration of synthetic materials, such as rubber and plastics, which lead to the formation of dioxins, furans, and polycyclic aromatic compounds. Subsection “[Open Burning](#)” elaborates more on the impacts of open burning of waste.

Open Burning

Open burning is illegal incineration of waste under uncontrolled conditions practiced either by individuals or organizations either deliberately or unintentionally. Since open burning is an illegal activity, precise estimates of the waste amounts being openly burned are impossible. According to Kaza et al. (2018), who collected the data from different countries, the share of waste being openly burned is less than 1%, whereas the study by Wiedinmyer et al. (2014), who calculated the results based on various assumption and parameters described in their study, estimate that 41% of the MWS generated is illegally burned. Regardless of the actual number, open burning of waste is still a common practice in developing countries

and might even occur in industrialized countries as a result of an unintentional fire on a landfill or a dump site.

Burning usually occurs in an oxygen-depleted atmosphere, which is a result of waste self-compaction in large dumps. Such incineration conditions lead to incomplete oxidation of waste, thus resulting in the formation of toxic persistent organic compounds (POPs), such as dioxins, furans, benzenes, and polycyclic aromatic hydrocarbons, which also belong to POPs. The concentrations of POPs are significant and represent a serious threat to the health of humans exposed to the fumes from open burning. Also, greenhouse gases, particulate matter, and many other substances and compounds are released during open burning. Cogut (2016) elaborates in detail the impact of open burning showing that the developing countries, which suffer the most from the open burning, also do not have the capacity to eliminate open burning of waste.

Environmental Impact Assessment

Because landfilling is the least desired waste management option, a lot of studies consider landfilling as a default situation of waste management in their assessments of the environmental impacts of alternative waste management systems. With such an approach, alternative waste management systems are often given the credit from avoided waste disposal. However, considerations should be given to the type of waste being assessed, the types of the impacts, and to the operating environments. Landfilling of waste having a large share of organics has the highest impact on climate change due to generation of landfill gas. Since landfill gas could be utilized for electricity or heat generation, it is oftentimes considered in life cycle assessment studies, thus giving a credit to the landfilling system (Liikanen et al. 2018). Niskanen and Horttanainen (2012) showed that an improved gas collection could reduce the impacts on climate change by two-thirds compared to the baseline, whereas improved oxidation and improved utilization of

landfill gas only reduce the impacts by a few percentage. In a study by Niskanen et al. (2013), the authors showed that at landfill gas collection efficiencies above 77%, the impacts from landfilling become negative due to the substitution of energy produced from incineration of methane generated in landfills. Therefore, the policies for the reduction of the climate change impacts from disposal should aim at the reduction of the share of organic waste, which could be achieved through source-separation and at increased collection of landfill gas during long periods accounting for the long decay rates of some waste fractions.

However, landfills do not always have high impacts on climate change. Disposal of inorganic waste, such as ash or slag from waste incineration or incineration of other fuels, might be a more acceptable option than its extensive fractionation from the climate change points of view, since landfilling of inorganic materials does not release any biogas (Deviatkin et al. 2016). On the other hand, landfilling of inorganic materials leads to the loss of substances embodied therein, such as phosphorus or alkaline substances, which could be used to replace fertilizers or cement (Deviatkin et al. 2017; Havukainen et al. 2016). Furthermore, landfilling of ash leads to leaching of heavy metals contained therein, which could otherwise be immobilized if ash were used in the concrete production.

Summary

Final disposal of waste is a commonly practiced waste management method globally. It includes open dumping, open burning, landfilling, and a range of other, less often practiced methods. Final disposal accounts for 70% of all MSW generated globally. Considering the value embodied in waste and the environmental impacts from final disposal, especially from open dumping, which accounts for a substantial of 33% of all MSW generated, final disposal conceals an enormous potential for the reduction of environmental,

social, and economic impacts through its avoidance and use of waste secondary material.

The largest impacts from final disposal of waste originate from the occupation of soil and its pollution, pollution of groundwater, the release of airborne emissions, and presence of alien objects in the natural environment. These impacts are considerably reduced with the transition from historically widely practiced open dumping to more engineered landfilling. Landfilling of waste introduces a wide range of measures to reduce the impacts from waste disposal on the environment mainly through the prevention of leachate leakage and through mitigation of landfill gas release. Still, landfilling remains a sink of valuable materials, which could otherwise be recycled, thus avoiding extraction of virgin materials from nature, not to mention a limited lifetime of the protecting structures, which deteriorate with time and pose increased risks for the environment and human beings.

Definitions

There is a high variety of approaches and interpretations in the conceptual discussions of sustainability reporting. In line with the growing awareness of sustainability by practitioners, its definition continues to systematically evolve. Schaltegger et al. (2006) define sustainability reporting in terms of its practical process: as the publication of external reports, where management appoints sustainability goals, collects data, and displays their sustainability information, usually in the forms of printed brochures or electronic formats. Another notable definition is presented by Junior et al. (2014), focusing on its role as a communication tool: “sustainability reports are an important communication tool, focusing on environmental and social performances, between an organisation and its stakeholders.” Sustainability reports can usually be found among companies, data providers, sustainability research firms, pension consultants, investment firms with sustainability products, nongovernmental organizations, and academic institutions (Brockett and Rezaee 2012).

Introduction

The adverse environmental impacts from modern industrializations have been discussed and

warned of by scientists for a considerable amount of time. However, the conversations of companies presenting accountability of their impacts to society at large first gained prominence during the 1970s. This would create a new buzz among business academic and practitioners, slowly leading to a buildup of conceptual foundations (Gray 2001).

By 1987, the Brundtland Report was published. Titled “Our Common Future,” it was an evolutionary report which brought nations together to discuss sustainable development. It defined sustainability as “meeting the needs of the present without compromising the ability of future generations to meet their own needs” – a catchphrase to be often utilized by future sustainability actors (Keeble 1988). Unfortunately, sustainability reporting also faced considerable animosity within the industry during that period, so much so that discussions surrounding it stagnated.

By the 1990s, however, the trend had reversed. Talks of environmental accounting and reporting faced a considerable resurgence (Gray 2001). Notable achievements include the first Earth Summit in 1992, held in Rio de Janeiro. Another is the publishing of “Coming Clean” in 1993, the first report to combine environmental, economic, and social dimensions of corporate performance by notable organizations such as Deloitte Touche Tohmatsu International, International Institute for Sustainable Development, and SustainAbility. However, it must also be recognized that most of the existing sustainability reports still focused on traditional reporting issues, such as health and safety, employee relationship, and philanthropy and charitable donations (Kolk 2004).

While the 1990s busied itself with continuing the developments of environmental accountability, by the next decade, companies had broadened their concerns to economic, environment, employees, and community matters. It had certainly significantly evolved from its first inception during the 1980s, when separate environmental and financial report was considered a hallmark achievement (Kolk 2004). Since 1999, the rate of sustainability reporting from the largest 250 companies had grown significantly (Gray 2001). During this new millennium, social and

environmental accounting had finally been encapsulated within regulations and the psyches of most global organizations.

Benefits of Sustainability Reporting

Apart from its benefits to the environment and society at large – which in itself has also been questioned – sustainability reporting also brings significant benefits to companies. According to Rupley et al. (2017), disclosures on corporate social responsibility (CSR) information are substantially economically profitable for companies. It can provide higher credit ratings and create positive capital market reaction to disclosure regulations. Standards which eliminate or reduce disclosures have been proven to deprive capital market of value-relevant information. Additionally, when companies initiate voluntary disclosures, it also brings substantial benefits: it lowers firm risks, lowers costs of equity, lowers costs of debt, increases credit ratings, and increases stock market performance during times of financial crisis.

Other benefits of sustainability disclosures have been reported by Schaltegger et al. (2006, p. 302): as acts of legitimizing corporate activities, products, and services that have produced environmental and social impacts; drives an improvement in corporate reputation and branding value; increases competitive advantage; and, finally, serves as a driver for an overall increase of transparency and accountability within the organization and its employees.

The Sustainability Reporting Process

Overall, the process of corporate sustainability reporting is rather simple and straightforward, similar to conventional reporting process. However, complexities arrive when looking at the particular details. For example, the industry sectors where companies belong to can significantly influence the different sensitive topics it may face, leading to different external pressures and criticisms. If a company isn't careful, or lacks

awareness of the sensitive topics, it can cause severe backlash from civil societal watchdogs and the general public.

At its core, sustainability reporting mainly consists of three objects: inputs, process, and outputs. First, inputs consist of source documents, events, and performance transactions. Second, processing objects measures and reports activities based on sustainability reporting guidance. Finally, outputs are recognized as sustainability reports which communicate company performances pertaining to financial and nonfinancial key performance indicators (KPIs) (Brockett and Rezaee 2012, p. 41).

Reports should also disclose both the positive and negative performances of the company's overall sustainability vision, such as successes and shortcomings of its sustainable programs, overall organizational risks and opportunities, changes during reporting to provide a better overview of (economic, governance, social, ethical, and environmental EGSEE) performances, the different policies to support its sustainability goals, and, finally, problem-solving methods to tackle any potential environmental and/or social impacts (Brockett and Rezaee 2012, p. 42).

Different Types of Standards in Sustainability Reporting

There is a wide breadth of different standards for the process of sustainability reporting. The following is not an exhaustive list but instead only includes two of the most notable types of standards widely used within industries: the Global Reporting Initiative (GRI) and Sustainability Accounting Standards Board (SASB).

GRI

The GRI, founded in 1997, was the first and, according to the organization, is the most widely used global sustainability reporting standards, with an adoption rate of 93% from the top 250 companies in the world (GRI a). The GRI organizes sustainability information according to the GRI's material topics, a set of standards companies have to provide in their disclosures. There

are two main categories: universal standards and topic-specific standards. The former consists of the GRI Foundations (GRI 101), General Disclosures (GRI 102), and Management Approach (GRI 103). It contains a series of guides to assist organizations in reporting their sustainable information. Meanwhile, topic-specific standards are further divided to three topic-specific standards: Economic (GRI 200), Environmental (GRI 300), and Social (GRI 400). Economic Standards include measurements on economic performance, anti-corruption, and taxes. Environmental Standards include topics such as energy, biodiversity, and emissions. Finally, Social Standards include information on employment, diversity, and marketing (GRI b).

SASB

Another prominent organization dealing in assisting companies to report sustainability matters is the SASB. For SASB, the organization categorizes sustainability topics into five sustainability dimensions. First is environment, which tackles issues such as natural resource inputs to production or pollution caused by companies to the environment (SASB n.d.). Second is social capital, which refers to the overall management of social relations companies have with society, for example, with customers, local communities, and vulnerable groups. The third dimension is human capital, which deals with companies' human resources, such as employees and contractors. Issues include employees' productivity and the health and safety of employees. Fourth is business model and innovation, which organizes issues such as product innovation, efficiency and responsibility in products, and disposal of products. Finally, the fifth sustainability dimension is leadership and governance, which manages issues of regulatory compliance, conflicts of interest, and corruption and bribery (SASB n.d.).

Other organizations which deal with sustainability reporting assistance, standards, and regulations include the United Nations Principles for Responsible Investment (UNPRI); the International Integrated Reporting Committee (IIRC); "Commission Guidance Regarding Disclosure

Related to Climate Change," a report published by the Securities and Exchange Commission (SEC); and "ISO 26000," or "guidelines for social responsibility reporting," developed by the International Organization for Standardization (ISO) (Brockett and Rezaee 2012, p. 29; Camilleri 2017).

Sustainability Reporting Around the World

While the first developments and sharing of ideas within the topics of sustainability and sustainability accountability occurred within the more advanced markets within Western hemisphere, it has recently taken progress to other parts of the world. Japan leads the way for sustainability reporting in a non-Western cultural setting, while countries in Asia, Latin America, and Africa are still struggling to find their feet in implementing standardized sustainability disclosures, whether in terms of regulations or initiatives (Amran and Haniffa 2011).

There is a substantial amount of differences between disclosures in developed and developing economies. In terms of the determining factors that propel companies to disclose their CSR activities, stakeholders such as regulators, shareholders, environmentalists, and the media play a large role in deciding the extent of sustainability disclosures for advanced markets. For emerging economies, disclosures are more determined by external stakeholders, such as foreign investors, international media, and international regulatory bodies (Ali et al. 2017). This is actually quite understandable, given that emerging economies face similar hardships in codifying and enforcing regulatory foundations not only in sustainable disclosures but also in other aspects of social and political spheres. Corruptions, incompetent public officials, and civil unrest are just one of the few issues faced by governments and market regulators in developing economies. Therefore, the regulatory gaps that exist are instead left to global regulatory bodies or organizations where the regulatory standards are already in place.

The following is a short excerpt of the developments of sustainability reporting around the world.

Sustainability Reporting in North America

In a study comparing sustainability reporting between North American, Asian, and European oil and gas firms, it was found that North American firms had the highest numbers of disclosures. Specific topics that North American firms focused on were environmental fuel consumptions, internal stakeholders, and shareholders (Gill et al. 2008).

Sustainability Reporting in Europe

In a comparison of corporate sustainability reporting between Central-Eastern and Western Europe, Steurer and Konrad (2009) found that the Western Europe countries had significantly higher numbers and extents of sustainability reporting. This was found to be determined by sociopolitical and socioeconomic conditions.

Sustainability Reporting in Asia

In a content analysis study of Asia Pacific countries by Amran and Haniffa (2011), South Korea, Japan, and Thailand led the way in terms of sustainability reporting, while Hong Kong and Indonesia produced poorer results. Companies that had larger firm sizes belonged to industrial membership, had a more advanced economy, or had stricter disclosure regulations, as well as their association with environmental certifications (Cormier et al. 2005). Meanwhile, in a study by Choi et al. (2013), Australian companies' carbon emission disclosures were found to have significantly risen over time, especially from the national regulation of National Greenhouse and Energy Reporting Act (the NGER Act) from 2007.

Sustainability Reporting in Latin America

Ortas and Moneva (2011) analyzed the sustainability reporting of Latin American countries, consisting of Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Ecuador, Mexico, Panama, Peru, and Venezuela. There had been

extensive growth of the total number of sustainability reports, while there had been only 30 GRI reports between 1999 and 2004; by 2009, it had risen to 489 reports. Among them, Brazil, Chile, and Mexico lead the number of disclosures.

Sustainability Reporting in Africa

A study conducted by Dawkins and Ngunjiri (2008) identified that corporate social responsibility reporting (CSRR) of South African companies was found to be substantially higher than the reporting implemented by the Fortune Global 100. For South African companies, positive benchmark performances in the dimensions of diversity, community, and employee relations were found to be considerably higher than the top 100 global companies.

Sustainability Reporting in the Middle East

Although the literatures surrounding sustainability reporting in the Middle East remain scarce, there have been a surge of developments. In a study by Nobanee and Ellili (2016), sustainability disclosures of United Arab Emirates listed banks, between 2003 and 2013, were measured. They found that, generally, sustainability disclosures were quite low. They also found that there were higher extents of reporting for conventional banks, compared to Islamic banks. Indeed, for the former, sustainability disclosures had considerably and positively affected banking performances, although no effect was found for the latter group.

Criticisms

Overall, the evolution of sustainability reporting reflects a significant progress of corporate attitudes to their environmental and societal impacts. It manages to provide a different portrayal to the business industry as a whole not only as a caricature of greed and profit-driven villains but as social change actors, driven to bring positive ecological and social impacts. However, is this transformation justified, or does it only portray a

problematic emblem of new, meaningless, business slogans? Sustainability reporting is not without their fair share of criticisms. According to Milne and Gray (2013), the gap between the practices of corporate sustainability reporting and the very act of sustaining humankind's ecological survivability is too large. Although there has been the conceptualization of "triple bottom line" (TBL) in business industries and other movements, business idea of corporate sustainability has overridden the actual realities of ecological concerns. Even among notable standards developed by SustainAbility, KPMG, and GRI, the mountainous copies of sustainability reports are seen as inadequate in terms of their purpose for environmental preservation. They may actually accomplish quite the opposite, promoting the view that everything is alright in ecological terms, and may inherently advocate business-as-usual practices for companies.

Summary

There is no denying that sustainability reporting has come a tremendously long way since its inception. However, is the progress of sustainability reporting over the decades, put simply, enough? Enough to turn around the impacts of anthropogenic climate change, along with air and pollution and loss of biodiversity – as a result of the history of massive unaccountable industrializations? It has the potential to, of course, as with other sustainable measures – but only with strict and extensive scenarios of several "if's": If companies are able to curb their productions and manufacturing of polluting or nonrenewable resources, if increasing sustainability regulations can be effective in swaying the behaviors of troubled companies and bring powerful legal repercussions, and if societies can be motivated to significantly decrease their volumes of consumptions. Unfortunately, our only method of deciphering whether the developments of sustainability reporting have been successful in ecological and social transformation is within the confinements of the future.

Description

Sustainability reporting guidelines (see also Reporting Frameworks) provide aid for organizations in the preparation of sustainability disclosures (Searcy and Buslovich 2014). They define reporting principles ensuring high quality of disclosure as well as specific indicators measuring sustainability performance. Their emergence is one of the major forces driving the development of sustainability disclosure understood as “the process of communicating the social and environmental effects of organizations’ economic actions to particular interest groups within society and to society at large” (Gray et al. 1987, quoted in Kotonen 2009) (see Corporate Social Responsibility Reporting; Sustainability Reporting; Sustainability Report & Sustainability Reporting; Sustainable Reporting). There is a variety of international and local initiatives that assist organizations with their sustainability reporting. While some of them may have a comprehensive scope, others focus on specific sectors or issues. The most widely recognized initiatives include (in alphabetical order) CDP, Climate Disclosure Standards Board (CDSB), European Commission □ Guidelines on Non-financial Reporting, UN Global Compact Communication on Progress (COP), Global Reporting Initiative (GRI), International Integrated Reporting Council (IIRC), Sustainability Accounting Standards Board (SASB), the FSB Task Force on Climate-Related Financial Disclosures (TCFD).

CDP

CDP, launched as **Carbon Disclosure Project** in 2002, provides the global online disclosure system for companies, cities, states, and regions that enables them to measure and manage their environmental impact. It primarily focused on GHG emissions but has expanded into water and forestry issues. The organization holds online repository of self-reported environmental data from entities worldwide. Additionally, it conducts annual scoring of corporate disclosers and

recognizes top companies that form **The A Lists**. The Climate A List was established in 2011. Later in 2015 and 2016, the scoring process was introduced also for water and forestry reporting, respectively (CDP 2021).

The CDP's data allows investors, businesses, and policy makers to evaluate environmental opportunities and risks and to make informed decisions. As for 2021 the organization's network included over 9600 companies, over 800 cities, over 130 states, and over 590 investors with 110 trillion USD in assets. CDP promotes and encourages, however does not require, third-party verification as an integral part of the disclosure process. The organization awards verified report additional points in the annual scoring process (CDP 2021).

Climate Disclosure Standards Board (CDSB)

The CDSB (2019) was formed at the World Economic Forum's annual meeting in 2007 as an international consortium of business and environmental non-governmental organizations (NGOs). One of the organization's board members is CDP (discussed above) that also serves as its secretariat. The CDSB offers framework for reporting environmental information in mainstream corporate reports (e.g., annual report or the Form 10-K). The framework is aligned with and complements the objective of financial reporting – it assists organizations in disclosing environmental information that is connected with their overall strategy, performance, and prospects. In this way, it aims at providing financial stakeholders with decision-useful and reliable information that can be utilized for the efficient allocation of capital.

The framework encompasses principles that guide the process of determining, preparing, and presenting environmental information. They indicate that the disclosure shall be (1) prepared applying the principle of relevance and materiality; (2) faithfully represented; (3) connected with other information; (4) consistent and comparable; (5) clear and understandable; (6) verifiable;

and (7) forward looking (CDSB 2019, pp. 11–16).

The CDSB Framework provides also reporting requirements that define the content of the environmental disclosure. According to the requirements, disclosures should include the following:

1. Description of the governance of environmental policies, strategy, and information.
2. Description of the environmental policies and strategy, as well as targets, timeline, and key performance indicators (KPIs) against which the company's performance is assessed.
3. Information on environmental risks and opportunities affecting the organization, as well as on how those are managed.
4. Information on performance (quantitative and qualitative results) together with measurement methodologies.
5. Comparison of the performance with the targets set and results reported in previous periods.
6. Outlook, i.e., management's conclusions about the effect of environmental impacts, risks, and opportunities on the company's capacity to innovate, manage risks, execute strategy, and create long-term value.
7. Definition of the organizational boundary for environmental information.
8. Description of the reporting policies used for preparing environmental information.
9. Information on the reporting period.
10. Restatements.
11. Statement of conformance with the CDSB Framework.
12. Assurance (in case it has been provided, which is not a requirement itself) (CDSB 2019, pp. 18–26).

European Commission Guidelines on Non-financial Reporting

In 2014, the European Union (EU) introduced the Non-financial Reporting Directive (2014/95/EU) that requires large public interest entities with over 500 employees (listed companies, banks, and insurance companies) to disclose certain

non-financial information. From the year 2017, around 6000 large companies and groups are obliged to publish statements on their environmental impact, social, employee and human rights issues, anti-corruption, and bribery matters, as well as diversity on company boards (EC 2020).

The Directive gives companies flexibility in terms of disclosure methodology. However, in order to assist companies in the reporting process, the European Commission (EC) issued in 2017 non-binding guidelines (EC 2017). EC's methodology is principle-based and universal for companies across all sectors. Its key principles indicate that non-financial information disclosed should be material; fair, balanced, and understandable; comprehensive but concise; strategic and forward-looking; stakeholder oriented; and consistent and coherent with other elements of the management report (EC 2017, p. C/215/5–9). The use of independent external assurance is recommended as a method to increase fairness and accuracy of disclosed data.

While defining the content of non-financial statement or report, the guidelines refer to the requirements of the Directive. The latter include business model, policies and due diligence, outcome of the policies, risks related to non-financial issues and their management, and KPIs (EC 2017, p. C/215/9–14). Although the guidelines include examples of KPIs that companies may use in particular thematic aspects, they do not provide specific indicators. In 2019, the guidelines were supplemented by a set of guidelines on reporting climate-related information (EC 2019).

UN Global Compact Communication on Progress (COP)

The COP is an annual disclosure through which business signatories of the UN Global Compact report on progress in implementing the ten principles of the initiative (see United Nations Global Compact). While the format of a COP is flexible (it can be a stand-alone document or a part of a sustainability or annual report), it needs to meet three minimal requirements (UNGC 2013, p. 1):

1. A statement by the CEO expressing continued support for the initiative and renewing the participant's commitment.
2. A description of practical actions (taken or planned) aimed at implementing the ten principles in each of the four issue areas (human rights, labor, environment, anti-corruption). If the company does not address one or more of the defined areas, it must provide an explanation ("report or explain" rule).
3. A measurement of outcomes (qualitative or quantitative).

Third-party assurance is not a requirement for the COP.

The COPs are categorized into three differentiation levels based on the depth of their disclosure:

1. GC Learner: COPs that do not meet one or more of the minimum requirements.
2. GC Active: COPs that meet the minimum requirements.
3. GC Advanced: COPs that meet the minimum requirements and provide information on additional advanced criteria in the following areas: implementing the UN Global Compact principles into strategies and operations; taking action in support of broader UN goals; corporate sustainability governance and leadership (UNGC 2013, p. 2).

The UN Global Compact provides a basic guide for preparing COP (UNGC 2019). The document introduces a simple COP structure, suggestions, and examples, which are also available as an online template to fulfill the minimum requirements for GC Active level. Advanced disclosers seeking to prepare more comprehensive report are encouraged to use the GRI reporting framework.

Global Reporting Initiative (GRI)

The GRI (see Global Reporting Initiative) has pioneered sustainability reporting since 1997. It offers the most widely used sustainability

reporting framework in the world (Clayton et al. 2015) that assists organizations (businesses, NGOs, and public institutions) in assessing their social and environmental impact and sustainability-related decision-making (GRI 2020). GRI Standards are based on the **triple bottom line (TBL)** (see Triple Bottom Line) concept (Robins 2006) that expands the traditional, financially focused accounting approach to include organization's social and environmental performance. Although the core GRI framework is designed for organizations of any size, type, sector, or geographic location, it is additionally supplemented by sector- and country-specific standards. The GRI has been announced as the recommended reporting framework of the UN Global Compact (UNGC 2010).

The initial set of the reporting guidelines (G1) was introduced in 2000. After 2 years, the second generation of the guidelines (G2) was released and referenced in the Plan of Implementation of the World Summit on Sustainable Development. 2006 and 2011 the third generation (G3) and its update (G3.1) were published, respectively. The latter was replaced by the fourth generation (G4) in 2013. Finally, in October 2016, GRI Standards (GRI 2016) as the first global standards for sustainability reporting were launched.

GRI Standards encompass three universal standards that are to be used by every organization preparing a sustainability report. These include *GRI 101: Foundation*, *GRI 102: General Disclosures* (requirements on contextual information about an organization and its reporting practices), and *GRI 103: Management Approach* (requirements on information about the approach an organization uses to manage a material topic). Additionally, reporting organizations choose from 33 topic-specific standards (*GRI 200: Economic*, *GRI 300: Environmental*, *GRI 400: Social*) in order to disclose information on their material issues. The GRI advises, but does not require, external assurance for sustainability-related data (GRI 2013).

The *GRI 101: Foundation* standard describes two groups of reporting principles:

1. Principles for defining report content that determines the process of selecting the content of the report, taking into account the activities undertaken by the organization, its impact, and the significant expectations and needs of its stakeholders.
 - Stakeholder inclusiveness.
 - Sustainability context.
 - Materiality.
 - Completeness.
2. Principles for defining report quality that determine the choices regarding the quality of information and its appropriate presentation.
 - Accuracy.
 - Balance.
 - Clarity.
 - Comparability.
 - Reliability.
 - Timeliness.

An organization preparing a report in accordance with the GRI Standards can choose one of two options depending on the degree to which the standards have been applied: (1) Core, obligation to report against *GRI 101*, *102*, and *103* and one disclosure for each material topic, and (2) Comprehensive – obligation to report against every disclosure for each material topic.

International Integrated Reporting Council (IIRC)

The IIRC comprises reporting organizations, regulators, investors, standard setters, academia, accountants, and NGOs. The coalition promotes integrated reporting (see Integrated Reporting, Integrated Reporting for Sustainability), defined as “a concise communication about how an organization's strategy, governance, performance and prospects, in the context of its external environment, lead to the creation of value over the short, medium and long term” (IIRC 2021, p.10), as a next step in the evolution of corporate reporting. The aim of this form of disclosure is to overcome shortcomings of traditional financial and sustainability reporting that, as some authors argue, have failed to provide holistic view of company's

operations (Lodhia 2014; Clayton et al. 2015). Integrated reporting focuses on the organization's ability to create value from different types of capitals, not necessarily owned by the company: financial, manufactured, intellectual, human, social and relationship, and natural (IIRC 2021). "In essence, integrated reporting is a hybrid practice that spans between the different worlds of financial reporting and sustainability reporting" (van Bommel 2014, p. 1158).

In its International <IR> Framework, firstly published in 2013 and updated in 2021, the IIRC sets principles guiding integrated reporting, as well as defines the overall content of an integrated report. The Framework provides seven guiding principles (IIRC 2021, pp. 25–37):

1. Strategic focus and future orientation – reporting organization should present its strategy, how it relates to value creation in different time horizons and to the use of and effects on the capitals.
2. Connectivity of information – an integrated report should show interdependencies between financial and non-financial information in order to provide the holistic picture of the organization's value creation process.
3. Stakeholder relationships – an integrated report should present stakeholder engagement process.
4. Materiality – issues disclosed in an integrated report should be identified based on their effect on the organization's ability to create value over the short, medium, and long term.
5. Conciseness – information should be provided in a concise way.
6. Reliability and completeness – all material matters, both positive and negative, should be disclosed in an integrated report.
7. Consistency and comparability – information should be presented in a consistent way that enables comparison of organization's performance over time and with other entities.

While the IIRC's Framework is principle-based, it does not provide organizations with any specific indicators for integrating non-financial and financial data or does it require third-party

assurance of non-financial data. Nevertheless the latter is encouraged by the IIRC, as it is viewed as a fundamental mechanism enhancing credibility and reliability of integrated reports (IIRC 2014).

According to the IIRC's Framework, an integrated report should include eight content elements (IIRC 2021, pp. 38-):

1. Organizational overview and external environment – presentation of what organization does and the context of its operations.
2. Governance – information on governance structure and its impact on organization's capability to create value.
3. Organization's business model – description of inputs, business activities, outputs, and outcomes.
4. Risks and opportunities – identification of key risks and opportunities that affect the organization's value creation process and description of how those are managed.
5. Strategy and resource allocation – future-oriented information regarding organization's strategic objectives and resource allocation plans.
6. Performance – qualitative and quantitative information on performance related to strategic objectives and impact on the capitals.
7. Outlook – information on challenges and uncertainties that the organization is likely to encounter and their potential impact on business model and future performance.
8. Basis of preparation and presentation of the report's content.

Sustainability Accounting Standards Board (SASB)

The **Sustainability Accounting Standards Board (SASB) Foundation** was founded in 2011 as a non-profit standards-setting organization (SASB 2020) with mission to help companies communicate financially material and decision-useful information to investors. Provisional version of Sustainability Accounting Standards was published in 2014. Three years later, the organization issued an exposure draft of the standards.

Their codification and final release took place in November 2018. The SASB provides standards for 77 industries across 11 sectors ensuring comparability of information across companies within an industry (SASB 2020).

The SASB's framework focuses on the industry-specific sustainability issues (both environmental and social) that have financial impacts and therefore are relevant to capital providers (SASB 2020). The SASB's intention is to provide investors with assistance in integrating sustainability information into fundamental analysis, comparison, and portfolio management. Standards are addressed to US public companies and can be used on voluntary basis to disclose information to investors in SEC filings (SASB 2017a).

SASB conceptual framework is based on three basic principles: (1) evidence-based, assessment of sustainability topics materiality is based on evidence-based research; (2) market-informed, standards are shaped in consultation with participants in capital markets (issuers and investors); and (3) industry-specific – standards focus on sustainability issues at the industry level (SASB 2017a). Reports prepared according to SASB standards are expected to have the same level of rigor and accuracy as all other information contained in financial filings. The SASB suggests that companies should consider third-party assurance but does not explicitly state that such assurance is necessary to enhance the credibility of the sustainability disclosure (SASB 2017b).

The SASB introduces a five-dimensional classification of sustainability issues: (1) environment, environmental-related impacts on company's financial condition or operating performance; (2) social capital, management of relationships with key external stakeholders focused on gaining legitimacy; (3) human capital, management of company's human resources and its impact on organization's long-term value; (4) business model and innovation, integration of environmental, human, and social issues in company's business model; and (5) leadership and governance – management of issues that are inherent to the business model and that are in potential conflict with stakeholders. As a subset of those general

categories, each SASB industry-specific standard defines disclosure topics tailored to the context of particular industry (SASB 2017a).

The FSB Task Force on Climate-Related Financial Disclosures (TCFD)

In 2015 the Financial Stability Board (FSB) established an industry-led disclosure task force on climate-related financial risks with American politician, businessman, and philanthropist Michael R. Bloomberg as chair and private sector individuals from financial and non-financial companies as members. The TCFD's aim is to develop recommendations for voluntary reporting on climate-related financial risk. Recommendations allow companies assess and manage their risks, as well as assist financial stakeholders including investors, lenders, and insurers in effective capital allocation. It is believed that higher transparency in regard to financial impact of climate-related risks strengthens the stability of the financial system and contributes to transition toward sustainable economy (TCFD 2015).

Final Recommendations of the Task Force on Climate-Related Financial Disclosures were issued in 2017 (TCFD 2017a). They are intended for companies that wish to voluntarily disclose climate-related information in their mainstream annual financial filings. The TCFD defines seven principles for effective, high-quality disclosure that should (1) represent relevant information; (2) be specific and complete; (3) be clear, balanced, and understandable; (4) be consistent over time; (5) be comparable among companies within a sector, industry, or portfolio; (6) be reliable, verifiable, and objective; and (7) be provided on a timely basis (TCFD 2017b, p. 18).

The guidelines are structured around four core elements:

1. Governance – the governance of risks and opportunities related with climate change.
2. Strategy – the impact of these risks and opportunities on the organization's businesses, strategy, and financial planning.

3. Risk management – the identification, assessment, and management processes of climate-related risks.
4. Metrics and targets – the metrics and targets set for assessment and management of climate-related risks and opportunities (TCFD 2017b, pp. 13–15).

Additionally the TCFD recommends using scenario analysis as a tool to assess medium- and long-term strategic implications of climate change. The organization provides technical supplement to assist companies in climate-related scenario analysis consistent with the TCFD guidelines (TCFD 2017c).

Similarly to other guidelines, TCFD Recommendations does not impose requirement for independent external assurance. However, “disclosures should be subject to internal governance processes that are the same or substantially similar to those used for financial reporting” (TCFD 2017b, p. 53).

Criticism

Critics of the present sustainability reporting guidelines raise concerns related with poor quality of information disclosed by the companies. Flower (2015) argues that for firms to publish complete, correct, and comparable information on sustainability performance, two conditions must be met: (1) firms should be provided with reporting standards which would assure comparability and completeness of reports; (2) firms should apply these standards correctly and consistently. While the first condition is generally met, the second remains problematic. Empirical evidence (Boiral 2013; Macellari et al. 2021) shows that although companies claim to prepare their sustainability reports according to specific guidelines, they often do not faithfully apply them. In result, sustainability reports, even those externally verified, lack credibility and balance and fail to present fair view of firm’s performance.

Another concern refers to the proliferation of many different guidelines that put severe disclosure burden on companies. This leads business to

concentrate more on the so-called box-ticking and detracts from investing in initiatives that could actually drive real change to global social and environmental problems (Vives 2016). Some argue that efficacy of sustainability reports is low “due to the confusing glut of standards and frameworks” (Leinaweaver 2015).

Sustainability Resilience

Antonio Castrofino

Unitelma Sapienza University, Rome, Italy

Definition

The term resilience (from the Latin “resiliens-entis” and has the meaning of “bouncing”) takes on different meanings based on the context within which it is used. Often this term is used in engineering, psychology, computer science, and biology. When we talk about resilience in biology, the term describes a body’s ability to self-repair after suffering damage and returning to its original state. In natural environments, it is the ability of ecosystems to restore their initial state, or create a new equilibrium, after a shock.

Introduction

Resilience is defined by scholars as “the speed with which a community, an ecological or socioeconomic system returns to their initial state, and they do so by innovating, after having been subjected to a shock, caused by natural events or anthropogenic activities” (Mezzi and Pelizzaro). The difference between resilience and

sustainability is that sustainability seeks a new balance between man and planet while resilience acts in a reality that is not in balance (Zolli 2012). The current climate changes place human civilization in front of a great crossroads. The development model applied globally in the last two centuries has had a negative impact on the ecosystem balance of the planet. Today the challenge that humans are called to collect as a human community is to transform the current development model into a model capable of being sustainable and of repositioning the environment and nature at the center of global policies.

In this global context, resilience is part of the environmental sphere. Among the interests of the studies, man becomes a reality by trying to solicit political institutions to find solutions to prevent damage and to structure adaptation programs that provide a great deal of opportunity in all situations to restore a negative pre-event balance.

Strong heat waves, sudden “water bombs,” floods, exploitation and waterproofing of the soil, advanced deserts, deforestation, and melting of glaciers and arctic poles are some of the biggest problems that endanger natural ecosystems and same human civilization.

For this reason, it is fundamental to succeed in the near future in finding solutions capable of remedying these dangers while safeguarding the Earth’s homeostasis.

The Value of Resilience

Johan Rockström, one of the fathers of resilience, along with a team of 26 other scientists, described the Earth as a dynamic system that has multiple states of equilibrium and its resilience. Rockström developed the “the quadruple squeeze,” that is, it identified four stress factors strongly linked to resilience: the human population growth, the climate change, the decline of ecosystems, and the “surprise” factor, which is part of the unpredictability of events (Rockström and Karlberg 2010).

Rockström and his team have also tried to outline real “planetary boundaries” in which

humanity is all within sustainable development. The insurmountable boundaries traced by the team are nine: the rate of biodiversity loss, the level of ocean acidification, the rate of land exploitation, the rate of consumption of freshwater, the level of ozone in the atmosphere, the economic change, the level of chemical pollution, the balance in the nitrogen and phosphorus cycles, and the amount of atmospheric particulate. Since the 1960s of the last century, we have crossed the border of the cycle while in the 1990s that of climate change and the loss of biodiversity while others are getting closer to being overcome.

Nature, in addition to being a physical universe, is the set of delicate balances in which flora and fauna coexist completely interconnected together, adapting to atmospheric and climatic conditions.

The human being, since its appearance on earth, has always had an impact on nature by changing the environment in which it carried out its activities. Its impact on ecosystems has been growing over the centuries up to the last two centuries, with the two industrial revolutions, the advent of the oil age, globalization, and the world population growth, accelerating the exploitation of resources and creating significant changes to ecosystems, damaging their delicate balances even irremediably.

The speed with which this crisis has arisen derives from the model of human development which, in search of growth and consumption without limits, has not taken into consideration the natural cycles and the real capacity of renewable resources to regenerate. Furthermore, the continuous exploitation of nonrenewable resources, with products that quickly become waste, will generate their exhaustion in ever-faster times. The damage, therefore, and the stress that man causes to ecosystems mean that a change of course concerning the current development model is fundamental.

World population growth over the last 100 years has been very important and has reached updated levels (Livi Bacci 2016). In 1800 there were about 1 billion inhabitants on

Earth. On the eve of 2000, this number grew to around 6 billion inhabitants, and the estimated number is still growing by 2050 when about 9 billion inhabitants will be counted on Earth. This growth was possible thanks to the improvement in the quality of life, medical discoveries, and the “Green Revolution” in agriculture. However, current population growth is not sustainable in the long run from the limited resources of our planet.

The NGO “Global Footprint Network,” analyzing the data in its possession, tells that in the last 70 years, the “Overshoot Day,” that is the day on which the human being ends the world natural resources produced by the Earth in a year, is always registered before the expiration of a period of 365 days.

The broader concept of resilience understood as the speed with which a community, an ecological system, returns to its initial state by innovating after a shock due to natural causes fits into this context. Resilience has three key dimensions that characterize it:

1. The bounce
2. Adaptation to variability and uncertainty
3. Positive transformation

The first dimension, or “*bouncing*,” refers to the narrower meaning of resilience. A body that has received a shock regains stability and returns to its initial state. Today, this concept should be implemented within human communities. As a crisis, an environmental disaster, a shock, they hit the community; it must react to the shock until it returns to a situation of pre-shock balance. However, this scenario is not yet achievable with the same capacity by all the communities that live on our planet. In the reports that the IPCC, Intergovernmental Panel on Climate Change, periodically presents to the global political community, it is highlighted how the climatic changes caused by man will not have a homogeneous impact on the entire human race. The richer communities will cope with more resources and technologies to extreme events than the planet’s indigenous and poorest populations. The latter will pay the

highest price if nothing is done to stop the global climate crisis.

The *adaptation to variability and uncertainty*, then, brings with it the idea of structuring and planning political actions toward higher attention to the risks to which extreme weather events subject communities (Pelling 2011). There is the talk of adaptation plans to deal with environmental crises in rural, agricultural, and above all, due to the high concentration of people, citizens. Cities are today the main center of attention of resilience scholars. In their construction and the thought of their development, the attention necessary to limit crises is too often missed. Suffice it to say that in the face of extreme events such as water bombs, the streets of our cities often become real rivers, which in the case of heat waves, at risk is the health of the weakest people.

In the recent past, there have been many initiatives to share good practices of urban resilience (Coppola 2016). 100 resilient cities is an organization dedicated to helping cities around the world to become more resilient and to respond to environmental, social, and economic questions. In the same way, the ICLEI – Local Governments for Sustainability, an international association of local services, has managed a program that focuses on urban adaptation mitigation issues.

The last dimension is that of *real change*, the positive transformation that resilience must bring within human communities. We are now talking more and more about “ecological transition” when we want to define the new path that many companies, communities, and institutions have begun to follow to implement concrete actions in contrast to climate change. The C40 Cities climate leadership group network is the most important and largest network of cities committed to combating climate change and reducing greenhouse gases. In its 10 years of life, it has brought together the largest cities in the world by bringing their mayors into contact and providing services in six areas of activity: adaptation and water; power; finance and economic development; waste management; urban planning and development; and transport.

Key Issues

Climate changes, vulnerability, uncertainty, extreme weather events, melting of glaciers and sea level rise, exploitation of resources, pollution, heat islands, absence of public green, soil sealing, degradation and abandonment, construction and building abuses, and neglect of the territory are all problems that the communities all over the world will face soon.

Future Directions

The study of resilience already brings an important set of proposals and policies that try to change the existing reality. “Ecological” resilience is intertwined with “social” resilience. Scholars hope that in the coming years, new ideas will always come out of the in-depth analysis of the systems and their interconnection to enable science and politics to give ever-better answers to environmental problems. The challenge of those who will seek the right path to combat climate change, with the objective of achieving a true ecological transition as soon as possible, will increasingly be able to deal with stressors and shocks. It will ask to reduce the factors that make a community vulnerable and to reduce the fear of uncertainty, increasing adaptation and securing territories and cities. Many technological tools are already available in many countries. A large influx of technological innovation is expected in the near future from developing countries as they are often victims of extreme events, even of a catastrophic nature.

Communities will have to build a real “resilient mentality.” Psychologists, neuroscientists, and sociologists are already working to study and discover factors of resilience in the field of human relations, of the human being in itself, and in the relationship with others. It counts in being resilient the network of people to which we refer, to the lifestyle that takes place, at the cultural level, and to religious affiliation (Ungar

2011). Resilience in psychology recalls an individual's ability to positively overcome traumatic events. Social and ecological resilience will be the basis of future policies.

Summary

Resilience is the ability of a body to return to a state of equilibrium after suffering a strong disturbance. With climate change underway, with extreme weather events increasingly frequent, scholars have begun to apply this concept to the study of ecosystems. Soon it will be important to try to apply policies to adapt to climate change, as well as sustainable development, to reduce the risk and the situation of vulnerability experienced by many territories around the world. The human being must therefore apply a concept of “ecological resilience” intertwined with that of “social resilience”.

Definition

Sustainability science is an academic discipline focusing on understanding complex social-ecological systems in order to enhance solutions-oriented decision-making and the ability of institutions and citizens to pursue a sustainable future for human and nonhuman entities that interact with each other.

Evolution of Sustainability Science

Sustainability science is a growing branch of science. The evolution of sustainability science began 20 years ago as a solution proposed by the scientific community to better understand cross-disciplinary boundaries in tackling global sustainability issues such as climate change. The notion of sustainability science was established as an international science policy project during the World Summit on Sustainable Development in 2002. It announced a shared vision of bringing

together different branches of science for reaching sustainability and consolidating the bond between science and society (Clark and Dickson 2003; Jäger 2009).

Three priority themes formed the basis for the evolution of sustainability science: (a) developing a research frame for sustainable development, drawing on a planetary point of view to create a shared understanding of the interconnectedness of society and environment; (b) carrying out targeted research on the understudied key questions that are critical for gaining a deeper understanding of the interconnectedness; and (c) linking knowledge to action for achieving transformative change toward sustainability (National Research Council 1999).

There are two orientations to sustainability science: environmental and developmental (Bettencourt and Kaur 2011). Kates et al. (2001) determined the basis for sustainability science by specifying three targets: (a) exploring the interactive system between the human and nonhuman worlds; (b) guiding human and nonhuman interactions; and (c) promoting individual, social, and institutional learning to navigate the transition to a sustainable future. Taking a more detailed look, ten fields of sustainability-related research were identified through meta-analysis. The human dimension of research included economic development, health, and lifestyle. The nonhuman world was presented by climate, biodiversity, agriculture, energy and resources, fishery, forestry, and water. These provided the foundation for a research framework for the following aspects of sustainability science, “goal setting, indicator setting, indicator measurement, causal chain analysis, forecasting, backcasting, and problem–solution chain analysis” (Kajikawa 2008, 231). Thus, one of the core questions of sustainability science is “How can the dynamic interactions between nature and society be better subsumed into emerging models and conceptualizations that integrate the Earth system, human development, and sustainability?” (Kates et al. 2001, 642).

Currently, sustainability science is based on understanding of systemic and transformative societal change to achieve the 17 sustainable development goals of the United Nations Agenda

2030 (UNESCO 2018). Smith et al. (2018) call for a “deep interdisciplinarity and transdisciplinary to support the indivisibility and universality of sustainable development” accordance with the sustainable development goals of Agenda 2030. According to Schneider et al. (2019), the scientific community willing to take on Agenda 2030 as a leading guideline should address the following tasks: (a) reflecting on the values, (b) elaborating how values are linked to activities, and (c) finding a common value-basis for sustainable futures. By doing so, the scientific community improves accountability and clarifies its ethical and epistemic basis.

Research in sustainability science combines human and nonhuman reality in order to understand complex social-ecological dynamics on local and global level (Miller et al. 2014). The field of research is administered by contributions from various disciplines and researchers with different world views, values, and paradigms. Thus, the concept of sustainability remains elusive, and its nature seems mostly indistinct (Joon and Oki 2011, 247). In this sense, sustainability science may be appropriately described as a meta-discipline, like the environmental studies in the 1980s (Caldwell 1983).

Comparing Different Approaches to Sustainability

Barriers to sustainability transformations often exist due to “complexity, uncertainty, and contested values” (Funtowicz and Ravetz 1993; also Rittel and Webber 1973). Interdependencies between human and nonhuman reality underscore the need for systems thinking. Systems thinking is associated with a holistic worldview. A person with a holistic worldview is able to interpret the world as an integrated whole rather than as a collection of individual pieces (Capra 1996). According to Capra (ibid.), the systems approach is a new paradigm in modern science. It is possible for the systems approach to become a science because “there is approximate knowledge,” which means that there are limitations in every scientific concept (Capra 1996, 41).

The concept of sustainable development is based on the idea of balancing environmental, social, and economic dimensions in research (O'Connor and Kenter 2019). In a decision-making situation, however, balancing of the dimensions in cases of trade-offs or conflicts is difficult. As a result of balancing, a sustainability transformation may result to *weak sustainability*. It prioritizes short-term well-being, well-being of nation, and linear economy. If we view the case from a scientific point of view, the vital ecosystem services provided by nature are essential for mankind's survival. The concept of *strong sustainability* assumes that the natural environment – as the basis for biodiversity and human and social well-being – is of primary and intrinsic value in sustainable development. In order to have a fair, efficient, and thorough transition to a sustainable future, Neumann et al. (2017) suggested that “an applicable and detailed concept of strong sustainability should be developed that holds for all natural capitals addressed in the 2030 Agenda and guides the implementation process ahead.” In other words, decision-making, policies, consumption habits of citizens, and any kind of human actions in accordance with the idea of strong sustainability should maintain, in the following order: first, diverse life; second, social justice; and third, a robust economy that is instrumentally valuable (Barry 2002; Bauman 2008; Hediger 1999; Kidder 1995; Marshall and Toffel 2005; Ott 2003). This could also be a question of temporal, regional, and material orientations, as demonstrated in Table 1.

Solutions that are in accordance with a strong sustainability approach thus prioritize long-term well-being over short-term well-being, planetary well-being over national well-being, and circular economy over linear economy.

Future Directions

Sustainability science helps us rise to the great environmental and developmental challenges of our time (Kates 2011). In this planetary transformation, the role of values and visions is essential. A key question is what *values* are related to wicked sustainability problems that societies face around the world. More specifically: What kinds of values are associated with a sustainable future and how can they be activated in a local and global level? And what are viable *visions* for sustainable future accordance with the Agenda 2030 and how do these visions translate into action? (Miller et al. 2014; Horcea-Milcu et al. 2019.) As an example, Society's Commitment to Sustainable Development (2016) shares a vision of the Finland we want by 2050, “A prosperous Finland with global responsibility for sustainability and the carrying capacity of nature.”

How have *socio-technical changes* been navigated in the past, and what strategies, tactics, and interventions could be promising in the future (Miller et al. 2014)? The Antarctic ozone hole is one of the most visible human impacts on the Earth. Since the implementation of the Montreal Protocol, research has shown that levels of ozone-destroying chlorine are declining, resulting in less ozone depletion (Strahan and Douglass 2018). The recovery of the ozone hole can now be seen as a success story of sustainability science, politics, and international cooperation (Sachs 2008, 113–114).

Values, visions, and socio-technical changes are a basis of the sustainability transformation which refers to the cultural evolution. In the future, solution-oriented research could be further emphasized in sustainability science (Sarewitz et al. 2012; Wiek et al. 2012). Further research

Sustainability Science, Table 1 Applying the concept of strong sustainability versus weak sustainability (adapted from Salonen and Hakari 2018)

	Strong sustainability	Weak sustainability
Temporal orientation	Long-term Well-being	Short-term Well-being
Regional orientation	Planetary Well-being	Well-being of nation
Material orientation	Circular economy (cradle-to-cradle)	Linear economy (cradle-to-grave)

could therefore be driven by the question of how citizens, society, and institutions can adjust their visions toward sustainable futures and implement just socio-technical change to achieve these ends. In order to support sustainability transformation, according to Miller et al. (2014), sustainability science can: (a) enrich the role of values in decision-making process; (b) support individuals, institutions, and societies in pursuing sustainability; (c) foster socio-technical transition (for example, in consumption and production); and (d) promote lifelong learning for education for sustainable development (Miller et al. 2014).

Continuous *learning* in society is at the center of a sustainable future. Phenomenon-based learning may be a way forward for facilitating transdisciplinary education in society (Lehtonen et al. 2018). According to UNESCO (2018), understanding of how transformative actions occur is the core of capacity building in a society. It is based on intertwined planetary reality. For example, peace is a question of social harmony and justice (Galtung 1969). Peace and sustainable development are closely tied to processes of globalization and socio-economic development. There is also an evident need to research the interconnectedness of sustainability and peace in the context of sustainability science.

Sustainability science is a solution-based interdisciplinary field of research. It deals with the deep systematic changes that are needed to meet the needs of present and future generations while building inclusive societies and conserving the planet's life-support systems. These changes permeate every dimension of society and touch the values and ways of every human life.

Frameworks; Guidelines; Standardization

Definition

Standards can be defined as predefined rules and procedures for organizational behavior with regard to issues that are usually not required by law. In general, standards are voluntary in nature, meaning that organizations have the discretion to adhere to standards or not. Standards can hence be seen as a form of self-regulation or “governance beyond government,” and this form of governance has gained much traction in recent years. Although not without critique, scholars, policymakers, and business leaders have recognized standards as a key instrument for effectively dealing with some of the world’s most pressing social and ecological challenges. From the perspective of companies, standards may function as an instrument that guides them in implementation

challenges, as a way to enhance the credibility of their claims, in benchmarking their performance and in communicating with stakeholders, among other functions. In the realm of corporate social responsibility (CSR) and sustainability, issues covered by standards encompass social and/or environmental issues, such as those reflected by the Sustainable Development Goals. Prominent examples of CSR standards include ISO 26000, United Nations Global Compact, Global Reporting Initiative, and SA 8000 and the AA 1000 standards series.

A World of Standards

The functioning of our modern world largely relies on standards. Standards can be defined as predefined rules and procedures for organizational behavior with regard to issues that are usually not required by law. They represent agreements of, shared interpretations on, and platforms for the self-regulation of organizations. Although organizations may in certain cases be required to adhere to one or more standards, many standards are voluntary in nature, meaning that organizations have the discretion to adhere to standards or not. Standards can hence be seen as a form of self-regulation by non-state actors or as “governance beyond government,” providing order without law (Terlaak 2007a). This does not imply that public organizations are categorically excluded from standards, whether it be standard setting, promoting standards, or adopting standards themselves. In fact, as forms of public-private governance, voluntary standards involving governments, non-governmental organizations, and businesses have gained much traction in recent years. Scholars, policymakers, and business leaders alike have recognized that private governance and public-private governance are key for effectively dealing with some of the world’s most pressing social and ecological challenges, notably those reflected by the Sustainable Development Goals. Hence, in the realm of corporate social responsibility (CSR) and sustainability, the use of standards is ubiquitous

among companies, addressing issues in the social and/or environmental domain. Some of the more well-known examples of such standards are ISO 26000, United Nations Global Compact, Global Reporting Initiative, and SA 8000 and the AA 1000 standards series. While these standards vary in type and have different characteristics, companies may also use standards for different reasons.

Function of (and Reasons for Using) Standards

Standards have received a lot of attention from scholars or organization science over the past decade. Academics have conceptualized and commented on their roles and functions from various theoretical lenses. According to Brunsson et al. (2012), from the perspective of organization studies, standards can be seen to contribute to the standardization of organizations, to be the result of standardization by organizations, and to refer to standardization as (a form of) organization. It is through standards and standardization (also in terms of the organization capacity of the human psyche) that people and organizations get to grips with the complexities and refraction of reality (Balzarova and Castka 2012).

Within these broad and abstract formulations of the goals and functions of standards, standards have been theorized to have several more specific functions for organizations, and indeed there are many reasons for organizations to adopt standards. From the overall goal of standardization efforts to enable reaching consensus on solutions that meet the requirements of business as well of the broader needs of society, standards can assist organizations in making legitimate sense of tangled problems, contested concepts, and multifaceted issues. Standards may hence serve a useful purpose in enabling organizations to interpret give meaning to their environment and their relationships to it, to structure their operations, to develop and implement policies, and to standardize strategic management processes (e.g., Rasche 2011; Hahn 2012). This function of standards may especially be useful in the context of CSR, which has

been dubbed as an essentially contested concept and lacking universal description (Okoye 2009).

Perhaps more importantly, the context of CSR standards may function as an indispensable signalling device for addressing problems related to the relative unobservability of a firm's CSR quality, understood as a firm's CSR commitments, actions, and performance (Johnston 2006; Terlaak 2007b; Perez-Batres et al. 2012). Through the reduction of information asymmetries that are inherent to CSR since stakeholders have de facto a different information position than the firms communicating about CSR, standards can assist in the interpretation and assessment of companies' CSR quality. As standards provide a common language and carry a legitimizing function, they can also function as a strategy to enhance the credibility of the CSR claims of companies (Castka and Balzarova 2008; Mueller et al. 2009; Mijatovic and Stokic 2010; Pflugrath et al. 2011; Delmas and Cuere-Burbano 2011). As an extension of this, standards may function as a platform for stakeholder dialogue, providing companies and their stakeholders an opportunity to and guidance in interacting about the issues they deem important and that demonstrate where their interest overlap (cf. Pedersen 2006). Also, through CSR standards, companies may differentiate themselves from competitors and secure legitimacy in their struggle for survival (Miles and Munilla 2004; Rasche 2011).

From a more practical point of view (see Moratis 2016), empirical research has shown that the most important functions of standards in corporate practice are to address the variety of CSR-related demands and expectations toward companies in a uniform and efficient way. Standards hence provide companies with an opportunity to "streamline" their relationships with society as a whole and their stakeholders. In addition, companies tend to view the function of standards as serving as a general point of reference or inspirational document for the development and implementation of CSR policies as important, while using standards as a differentiating strategy is not seen as important.

Types of Standards

The large number of standards, particularly in the CSR domain, that have surfaced over the past two decades does not make it easy to oversee the field. Against this background, it is useful to endeavor to classify the wide variety of standards. Rasche (2011) distinguishes between three different types of CSR standards: (1) principle-based standards, outlining broadly defined principles that are supposed to assist firms in reflecting on CSR (e.g., United Nations Global Compact); (2) reporting-based standards that outline performance indicators that companies can report on and that enable assessment against others (e.g., Global Reporting Initiative); and (3) certification standards that predefine compliance targets and compare a company's performance against these targets through audits (e.g., SA 8000).

While many standards fall within this categorization, it ignores the fact that usefully classifying standards can be based on other characteristics. For instance, it seems relevant to distinguish between internal standards and external standards, the former relating to self-defined standards (e.g., codes of conduct) while the latter relating to standards that have been developed by external, independent parties. Also, there is a difference between so-called management standards that particularly assist companies in implementation issues in very structured ways, usually concerning a certification element (e.g., ISO 14001), and guidance-oriented standards that merely provide suggestions for companies to address issues that are not suited for certification (e.g., ISO 26000). In the field of CSR, an important difference can be made between comprehensive CSR standards that aim to cover the entire range of CSR-related topics and issue-based standards which concentrate on one or sometimes a few closely related topics. Also, an important difference when looking at standards is whether they are first party (i.e., the company itself), second party (i.e., a certification organization paid for by the company), or third party (i.e., a stakeholder) audited or certified. The independence of the auditing or certification process may relate to

the perceived credibility of a company's CSR claims.

It should be noted that many competing standardization schemes have come into existence over the past years and that different versions of standards (or standards within a standards series) have been developed as well as new standards (with slightly different characteristics), having been modelled on an original standard. This has led to a marketplace for standards, allowing companies to "shop" and opportunistically choose between standards that are for the larger part similar when it comes to their contents but differ in legitimacy based on the organization(s) that developed the standard.

Critique

It should be noted that, despite their potential and widespread use, CSR standards are at the same time subjected to critique and even disdain. Adhering to such standards has been argued to represent a corporate strategy of abdicating rather than assuming responsibility – and to the extent it is viewed as a legitimate way for organizations to take responsibility, it has been dubbed a superficial way. Sceptics tend to conceive of standards as fig leaves and claim to witness many firms opting for low-exigency standards. Such corporate behavior would illustrate symbolic CSR implementation at worst and selective CSR implementation at best (Christmann and Taylor 2006; Mueller et al. 2009), compromising the degree to which standards reflect a firm's actual CSR quality. From a corporate communications point of view, standards may thus not improve the credibility of corporate CSR claims and not reflect the actual CSR quality of firms but rather be considered as a symbol of corporate greenwashing and the deceiving of stakeholders (cf. Laufer 2003; Ramus and Montiel 2005; Marquis and Qian 2014). Sceptics may also argue that CSR cannot be standardized as it is a too normatively oriented concept of which the value resides in idiosyncratic interpretations of the concept by individual firms that develop and vary over time.

Summary

Standards and standardization have important functions in both daily and organizational life. In the context of sustainability, too, standards and standardization are essential to guide and govern the behavior of organizations. This entry aims to enhance the understanding of sustainability standards and standardization through defining them, identifying their functions, suggesting a typology, and providing a brief critique.

Sustainability, Peak Oil

Stefania Massari, Marcello Ruberti, Federica De Leo and Pier Paolo Miglietta
University of Salento, Lecce, Italy

Synonyms

[Highest global oil production level](#); [Maximum level of crude oil production](#)

Description

In 1956, Marion King Hubbert, studying the trend of US oil reserves and production, elaborated a model and predicted that world production of conventional oil would peak around 2000. According to the Hubbert model, oil production in a large geographical region follows a symmetric, bell-shaped curve, at the top of which the peak is reached; this happens when approximately half of the available oil resources are extracted. Later in the 1990s, a new study about oil depletion was published by two petroleum geologists, and the peak oil issue started to receive a renewed interest around the world. Based on the same Hubbert curve, they predicted that oil production would have reached its peak around 2010 (Bardi 2019).

Even if in 2019 the predicted peak oil has not been reached at global scale yet and we can still count on oil, its supply has become less sustainable because it counts more and more on unconventional oil reserves, which require more expensive, complex, and environmental impacting, extraction, and production processes. The easily accessible and cheap crude oil seems to be in decline.

Introduction

Today, fossil fuels represent the most important global commodities and are essential for all human activities as they supply the majority of the total energy consumed by societies. Oil is the most important energy source in the world, and its main use at the moment is in the transport sector. It must be remarked that oil is not only used as a fuel, but it is also the fundamental raw material for the petrochemical sector which is at the basis of many other downstream industrial sectors, which produce thousand different products, such as plastics, textile fibers, dyes, detergents, drugs, etc. Petrochemical sector seems to be the main source of oil consumption growth. It has been calculated that even if the recycling rate of plastics doubled at global scale, this would result in a reduction of oil demand of 1.5 million b/d, compared to a

forecasted increase of consumption at global scale of five million b/d (IEA 2018).

According to the BP statistics, global oil production rose by 2.2 million b/d in 2018, and almost all of the net increase was accounted for by the USA, considered an absolute record. At the same time, global oil consumption grew by an above-average 1.4 million barrels per day (b/d), equivalent to 1.5%. The largest growth occurred in China (680,000 b/d) and in the USA (500,000 b/d), while important declines occurred in Venezuela (−580,000 b/d) and Iran (−310,000 b/d) (BP 2019).

The increase in oil prices does not reflect directly the scarcity of oil reserves, but it is linked to several technical, political, and economic factors. This is the reason why oil price cannot be used for making predictions about oil resources depletion, and different theories have been elaborated over the years about the peak oil. To predict the time when oil will be no longer available for human activities is very complicated due to the lack of reliable data regarding three aspects: the cumulative production, i.e., the quantity of crude oil which has been extracted until now; the estimate of the amount of oil which can be extracted from known fields; and the quantity of oil which still has to be discovered (Campbell and Laherre 1998).

The Peak Oil Predictions

In the field of fossil fuels studies, one of the most popular names is Hubbert.

Marion King Hubbert proposed his model and predicted the decrease of oil production, basing his assumptions on empirical studies about the production of coal and oil in USA, conducted until the time he presented his work in 1956. He stated that: "...the total amount of oil discovered is the sum of cumulative production and proved reserves. Since this is approaching the peak of the curve, the figure suggests that, even if we are less than half through in our exploration for petroleum, the period of declining rates of discovery has almost arrived" (Hubbert 1956). Hubbert applied his model to the production of oil in

USA and predicted that the production of oil would have reached its peak in 1970, while the production of oil at global scale would have reached its peak around 2000 (Bardi 2019).

Since that moment, a general fear started to circulate at global scale, and many studies were carried out in order to assess the most veritable time in which humanity would have faced the peak oil and then the irreversible decline in oil production. It has been argued later that Hubbert never proposed a theory that should have explained the reasons for his "bell shaped" curve. Many years later, Campbell and Laherrere wrote a paper titled "The end of cheap oil," in which they updated Hubbert's model with new estimates of oil reserves and predicted that the global crude oil production would have reached the peak around 2004–2005 (Campbell and Laherrere 1998).

This study also generated a movement of ideas called the "peak oil movement," followed in 2001 by the birth of the ASPO (Association for the Study of Peak Oil and Gas), constituted by different scientists and researchers, with the aim of studying and sharing knowledge about the peak oil, and alerting, at the same time, about oil scarcity (ASPO 2019).

All these predictions have been demonstrated to be only partially correct, especially because they did not take into account the huge importance that unconventional oil would have reached on the market later on.

The Role of Unconventional Oil

In recent years, the majority of new oil come into production derives from unconventional resources. Conventional oil is extracted through traditional process, based on single wells in which oil flows to the surface, almost naturally, thanks to the difference of pressure with the underground, or through the use of artificial lift mechanisms. A producing system for unconventional oil is instead more complicated, requiring more sophisticated recovery technologies and a completely different production scale (Deutch 2014). Unconventional oil includes: heavy oil, tar sands and

shale, or tight oil (Gordon 2012). All these unconventional sources require special extraction and production processes.

Usually when the price of oil is high, added to the uncertainty about the amount of reserves and the prediction of the peak moment, there is an increase in investments in innovative exploration and extraction techniques, and this in turn makes unconventional oil production competitive.

The annual flow rate of production is usually smaller for unconventional oil than for conventional oil, in addition to hugely capital-intensive nature of the production processes as well as bigger environmental impact (see environmental impact). For example, the hydraulic fracturing technique used to extract tight oil may constitute a risk for fresh water resources pollution; oil sands recovery requires a lot of energy and pollutes a lot of water (Hughes 2011).

For sure, the production of unconventional oil has given the opportunity to expand the global oil supply in the recent years, but this has happened with a substantially higher economic and environmental cost. Furthermore, many scientists agree that these unconventional sources are unlikely to offset the depletion of conventional oil production for long time (Alekklett et al., 2010).

A useful indicator for assessing the cost efficiency in the use of energy sources is the Energy Return on Investment (EROI). It has been calculated that EROI for discovering oil in the USA has decreased from more than 1000:1 in 1919 to 5:1 in the 2010s, and for production from about 25:1 in the 1970s to approximately 10:1 in 2007. Unconventional oil, such as tar sands and shale oil, gives a lower EROI, having a mean EROI of 4:1 and 7:1 (Hall et al. 2014).

Conclusions

Even if the exact date for peak oil is still unknown, we all should start to adopt alternative strategies to preserve oil reserves, to find better alternatives, use oil more efficiently, and save it just for the petrochemical use until we will be able to shift the world dependence from crude oil to biobased materials.

Rather than investing in searching new oil extraction sites, a better and more efficient alternative could be to introduce policies that reduce demand for fossil fuels by encouraging energy conservation and efficiency, using renewable electricity and biofuels (see energy biofuels) in the transport sector, using carpooling (see carpooling) and carsharing, and implementing intelligent traffic management measures. It has been calculated, for instance, that an efficiency improvement in traditional cars can bring a positive effect, in terms of reduction in oil demand, which is three times bigger than that given by 300 million electric vehicles forecasted in 2040 (IEA 2018).

Considerable savings of oil can also come by modal shifts from private vehicles to public transport in the case of passengers, and from road to rail in the case of freight (Wakeford 2012).

Summary

The prosperity and stability of modern society is strictly linked to the production and consumption of energy and especially oil (Tverberg 2012), which is still the world's largest energy source, providing 33% of global primary energy consumption (BP 2018). For this reason, scenarios and projections, regarding the availability of oil reserves, the production costs, and market prices, are very important for decision and policy making. The world has not faced the peak oil yet, and this is due especially to the exploitation of unconventional oil and the exploration activities in difficult geographic areas. So, even if human population can still count on oil supply, what has to be considered is at which conditions this happens. Easy and cheap oil reserves have been exploited already, and what we are using now are reserves of low-quality oil which is more difficult to extract, more pollutant (see pollution), and more expensive to work with; unconventional oil which needs very impacting extraction processes; and oil extracted from new fields discovered through expensive and impacting techniques, as in deep waters. So,

as much as oil production gets closer to its predicted peak, it becomes less and less sustainable.

Definition

The innovation process is related to the way innovation is conceived and produced, the different steps leading to innovation (creativity, marketing, research and development [R&D], design, production, and distribution) and the articulation between the different steps (Natário 2004). The innovation process is not confused with process innovations that correspond, according to the Oslo Manual (OECD/Eurostat 2018), to the implementation by the company of a production or delivery method new or significantly improved. The implementation of a new or significantly improved process does not need to be new to the market but should be for the company. It is not relevant if the innovation was originally developed by the company.

Sustainability arises in association with competitiveness, and it is regarded as a fundamental tool to acquire competitive advantages in the market (Pufal 2019). According to Pufal (2019, p. 17), it “becomes an essential prerequisite for the success and survival of companies and is only

achieved if it is an integral part of the organization's strategy."

Sustainable development is defined by UNCED that emphasizes the intergenerational balance: the capacity to satisfy the needs of the present generation without compromising future generations (United Nations 2018) (<http://www.sustainable-environment.org.uk/Principles/Definitions.php>).

Sustainable development is about being able to meet current needs without compromising future generations.

Therefore, business decisions should reflect the balance between the three dimensions of sustainable development: economic, sociocultural, and environment (Barbier 1987).

Key Issues

Since the 1980s, the linear approach to innovation processes has been questioned and progressively rejected to give way to systemic and interactive approaches. Presently, emphasis is given on the interactive nature of innovation, the complexity of the process, and the various feedbacks (Natário 2004).

The innovation process is no longer seen as a linear chain process with origin on applied research and sequence linkages. The linear and mechanistic process of innovation was abandoned by economists (Freeman 1987; Dosi 1988; Edquist 1997; Clark and Guy 1988; Cowan and Paal 2000; Conceição and Ávila 2001).

The linear innovation model shows that the relations between research and the market are organized in a sequential and linear way, starting from research to the market (Schumpeter's technology push model) or starting from the identification of market needs to research (Schmookler's market or demand-pull model) (Clark and Guy 1988; Kline and Rosenberg 1986). Nevertheless, this model presents some limitations: it is unidirectional and does not consider the numerous and complex loops, feedbacks, and interactions. The model is more suitable to explain the evolution of radical innovations but less that of incremental innovations. Nevertheless, it is the incremental

innovations that make the daily business of the company or the territory.

The linear model of innovation was contested and abandoned between the 1970s and 1980s when the systemic approach emerged (Lundvall 1992, 2010). Innovations result from a process of feedbacks from markets and user-producer interactive learning (Lundvall 2010). Innovation becomes a systemic process where networks and consumer/user-producer relationships lead to new forms of collaboration.

The steps leading to innovation are not linear and sequential, and the systemic approach overlaps. Innovation results from systemic linkages, with interactions between stages, and it is driven by forward or backward linkages between different functions and different innovation actors.

Therefore, the process of innovation is interactive (Lundvall 1992), resulting from the complex interaction between various actors and institutions; it is systemic (Edquist 1997) and cumulative (Cowan and Paal 2000): the technologies used in the present influence the learning process, and the dynamics of the accumulated experience and the future of the company will depend on what it has been able to do in the past in terms of accumulated learning and innovation.

In this context, a third innovation model, the multichannel interactive learning model, was presented by Caraça et al. (2009). For them, the "innovation process does not happen in a vacuum, but rather as a response to influencing, enabling and constraining factors. There is a near environment with actors and other organisations affecting the firm's innovation process - the micro environment, and in turn this is enveloped by a wider and evolving set of institutional structures, macro-economic, political, social, and ecological forces - the macro environment" (Caraça et al. 2009, p. 864).

Sustainability as a strategic tool to acquire competitive advantages in the market requires a proactive and innovative attitude of organizations and territories. In this context, the process of innovation is interactive and interdependent, cumulative, systemic, multi-actor, multidirectional and multicultural, and interdisciplinary, following the perspective of the third innovation model of

Caraça et al. (2009). Innovations, in turn, should seek to incorporate the balance between the three dimensions of sustainable development: economic, sociocultural, and environmental (Barbier 1987).

Future Directions

Future investigations may focus on the study of innovation process, as a systemic dynamic, incorporating the sustainability and social responsibility aspects, in order to respond to the growing challenges of companies and territories to obtain competitive advantages and not to compromise future generations, as advocated by United Nations report (2018).

Summary

This chapter covers the innovation process and its stages, highlighting the importance of sustainable innovation. In this sense, and in an evolutionary perspective, particular attention is given to linear and non-linear models of innovation, with emphasis on the interaction and systemic approach, integrating the dimensions of sustainable development.

Sustainable Brands

Elif Gulen Rady

Yasar University, Izmir, Turkey

Earth-friendly brands; Eco-friendly brands; Ecological brands; Green brands; Low carbon footprint brands; Low-waste brands; Viable brands; Zero-carbon brands; Zero-waste brands

Description

Without a doubt, there is increased customer demand across multiple industries toward more sustainable and greener products and brands. This increased customer demand has motivated brand owners to have a deeper look into the carbon footprint of their products and assess their environmental impact. In today's world, brand owners face the dilemma of either doing business as usual or changing business models to build more sustainable brands. However, old ways of doing business are becoming obsolete and irrelevant.

There have been two key milestones in history to establish responsibility for sustainability at a global level. In 1987, the Brundtland commission's report, *Our Common Future*, called for a new model of global economic development (Brundtland report 1987). The report offered what has become a common definition of sustainable development as development that "meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987; p. 41). This development can be considered as the first key milestone. Sharing a global footprint for sustainability, the

2030 agenda for sustainable development was adopted by all United Nations (UN) member states in 2015, which can be considered as the second key milestone achieved globally. According to UN's 2030 agenda, 17 SDGs illustrated the clear focus and dedication for the responsibility for environment and the humanity (United Nations 2020).

According to Porter and van der Linde (1995), the best choices for sustainable development that meet the needs of the society are environmentally and economically viable, economically and socially equitable as well as socially and environmentally bearable. As a matter of fact, many companies have organized their sustainability efforts around social, environmental, and economic dimensions.

Thus, sustainable brands can be defined as brands that have achieved to integrate social, environmental, and economic issues into their brand development, ecosystem, and business processes.

Main Dimensions of Sustainable Brands

According to Wanamaker (2018), social aspect of sustainability contains elements such as quality of life, education, community development, equal opportunity, law, and ethics. Economic aspect of sustainability contains elements such as smart growth, long-range planning, cost savings, R&D spending, and cost of living. And finally, environmental aspect of sustainability contains elements such as resource management, environmental protection, habitat restoration, and preservation. Along these lines, Sustainable Development Goal 12 is about responsible consumption and production, as shared by United Nations (2020) and provides guidelines to companies to help them better understand their environmental and social impacts of products and services, both of product life cycles and how these are affected by use within lifestyles. According to SDG 12, companies should identify "hot spots" in their value chains where there is potential to improve environmental and social impact (United Nations 2020).

According to Lynch and De Chernatony (2004), brands are a combination of emotional

and functional aspects that are perceived by customers as providing an incremental value, exclusive experience, and a fulfilled promise. These aspects make the brands an extremely powerful strategic asset for the companies (Kotler and Keller 2011). Integrating sustainable brand management into business practice can bring together the demands of customers, companies, and society and gain a win-win situation (Grubor and Milovanov 2017).

Summary

Sustainable Development Goal 12 (United Nations 2020) is about responsible consumption and production and provides guidelines for companies regarding environmental and social impacts of products and services, as well as the product life cycles and how these are affected by use within lifestyles.

Building sustainable brands and integrating sustainable brand management into business practice should be on the top of the agenda for business leaders in today's world. Brands are how external stakeholders perceive a company and its performance, and they constitute an important proportion of company's intangible value. Hence, they should be in the heart of sustainability practices of any company. Successful sustainable brand management can be an enormous advantage for marketers by differentiating their brands from those of competitors, adding incremental value, and generating more demand and intention to purchase more sustainable or green products (Mohd Suki 2016). One example of starting sustainable brand management is for companies to explain and communicate the environmental footprint of their products to their customers and other stakeholders. This practice can improve customers' knowledge and help assist their evaluation of sustainable products and brands (Rios et al. 2006). On the other hand, this practice can also enable companies to take a hard look into their products' footprint, and evaluate "hot spots" and

opportunity areas where an improvement can be made.

Definition/Description

A sustainable business model is a streamlined and combined illustration of the pertinent activities of a firm that expresses its logic, data, and other evidences that justify the customer value proposition and a revenue and cost-viable structure that implies the creation of monetary and non-monetary value for a wide ranging of stakeholders that incorporates proactively multistakeholder management.

From the Business Model Concept to Sustainable Business Model

Business model's definition is essential for business success and they can be seen as structured management tools (Wirtz et al. 2016; Magretta 2002). The concept of business model has developed, as Fig. 1 shows, and is still not completely understood as a research subject (Wirtz et al. 2016; Veit et al. 2014; Baden-Fuller and Mangematin 2013; Osterwalder et al. 2005).

There are many definitions of business model, even some of them agree regarding the central characteristics, even though the definition is diverse. A business model may be defined as a simpler and combined representation of the main and relevant activities of a firm. It gives you the description of how information, products, and/or services with market value is generated by the value-added component of a company (Wirtz et al. 2016).

For a clear comprehension of the business model definition is necessary, also to comprehend the relevant components of the business model (Wirtz et al. 2016). Analyzing the literature, we may observe a heterogeneous approach. Some authors (e.g., Hamel 2000; Bouwman 2003; Voelpel et al. 2004; Lehmann-Ortega and Schoettl 2005) pay attention to a minimum of aspects, others (e.g., Hedman and Kalling 2002; Yip 2004; Osterwalder et al. 2005; Osterwalder and Pigneur 2010) consider a more understandable perspective. But most of them agree on the components based in the market offerings and resources. Figure 2 shows the business model components outlined (Wirtz 2011) that should be understood as interrelated components.

This research area deals with the decomposition of the business model concept into partial models and components and the categorization of specific business models parameters. More recently the area of “innovation” is seen as an independent and self-contained concept in the literature (Wirtz et al. 2016). In this perspective of business model innovation, reinventing the business model can be leveled with the development or creation of entirely new business models

Sustainable Business Model, Fig. 1 Literature synopsis of the business model research. (Source: Wirtz et al. 2016)

Sustainable Business Model, Fig. 2 Components of an integrated business model. (Source: Wirtz et al. 2016)

(Voelpel et al. 2004) as opposed to only revising parts. For them, business model innovation occurs when a firm adopt a novel approach to

commercializing its underlying assets (Wirtz et al. 2016) and includes a more comprehensive approach and more revolutionary implication.

Even Voelpel et al. (2004) state that within the fast business evolution scenario new ways of sustainable competitive advantage can be accomplished from business model reinvention based on disruptive innovation and not only on incremental or continuous improvement.

In the management literature there is thus a clear linkage (Boons and Lüdeke-Freund 2013) between the business model of a firm and its innovation activities and innovation is strictly linked to the search of sustainability since is justified in normative concepts such as environmental sustainability or sustainable development (e.g., Boons 2009; Carrillo-Hermosilla et al. 2009, 2010; Hall and Clark 2003).

Sustainable Business Model

Due climate changes and environmental problems around the world, increase in the last years the pressures to the BM becomes more sustainable engaging more sustainable and smart innovation with positive and triple impacts on environment, society, and economy. Global pressures about global sustainability implies the collaboration between companies and stakeholders (Lowitt 2013). Sustainable business models can be considered as a subcategory of business models. Literature suggests different perspectives about sustainable business models (SBM). Bocken et al. (2014) argued that a triple bottom line approach is incorporated in SBM and reflects a wide ranging of stakeholder interests, involving environment and society. This perspective focused on the possibility of the companies promote, incorporate, and implement corporate innovation for sustainability as a key driver of competitive advantage.

Several authors provided a more complete definition of SBM including beyond environment their contribution for society (Lüdeke-Freund 2010) to improve quality of life (Garetti and Taisch's 2012). SBM obtains economic, social, and environmental value for a varied group of stakeholders (Bocken et al. 2013).

Another perspective about SBM is to discuss what it is business model innovations for

sustainability. According to the literature these innovations could be defined as innovations that produce substantial positive and/or meaningfully reduced negative impacts for the environment and/or society, through alterations of the organization methods and its generation of value network, deliver value, and capture value (i.e., create economic value) or modifications of their value plans (Bocken et al. 2014).

Additionally, business model canvas was developed attending to a sustainable perspective. Sustainable business canvas extended the original canvas by suggesting ten elements. This canvas BM includes the organizational effectiveness and efficiency perspective, positive and negative externalities, as well as productivity drivers (Sempels 2014), or summing up building blocks for a triple bottom line, which takes into account of the sustainability perspectives, i.e., incorporating environment, business, and society approaches (Dewulf 2010).

Figure 3 presents a sustainable business model based on four components: benefits (value proposition), value chain structure (how services are supplied), profitability model, and social and ecological awareness of the business.

The first step is to look at the value that the business idea can generate. A business model describes the potential value that would benefit the founder. The result of defining the value/benefit ratio will define the business. Products are part of the value chain structure and have a purpose in the market. The ability of a business to deliver extraordinary value through a product or service is a predictor of customer compliance.

In the second step, you need to answer the question: How to identify values for customers? The value chain structure is a description of the task listing partners and their roles. It answers the question: Who provides the service and how? For the business model to work, core competencies need to be carefully analyzed with the key business activities that will support those competencies.

The third step addresses the profitability model. In addition to what and how, the business model also describes how high the yield must be for the business to be ecologically sustainable and economically successful. It answers the question:

Sustainable Business Model, Fig. 3 Sustainable business model. (Source: Lindner, J./Fröhlich, G.: *Wirtschaft gestalten* Band II, 2015, p.28. (<https://www.oebv.at/produkte/wirtschaft-gestalten-hlw-ii-arbeitsbuch-bw>))

How does business generate income? Every business, even if it is not profit oriented, has to generate income to cover costs. The profitability model determines the cost structure.

The fourth step aims at social and ecological awareness because the sustainable business model only emerges through the integration of this step and will answer the question: How future oriented is the business plan? Sustainable management entails managing the business in a socially and ecologically responsible manner while ensuring that it is economically successful.

Profits will be realized by satisfying customer needs and lowering harmful environmental impacts, possibly through more efficient production procedures or diminished or changed consumption patterns.

Sustainability and Circularity in BM

As circular economy sustainability comes as a key factor to promote competitive advantage of companies. In this context circular economy implies a systematic innovation. According to Valkokari et al. (2014) the change toward sustainable and circular business model innovation should incorporate aspects from macro- (global trends and drivers), meso- (ecosystem and value co-creation), and microlevels (company, customers, and consumers).

A circular business model can be expressed as the reasoning of how an organization produces, delivers, and encapsulates value with and within closed material loops (Mentink 2014). Circular business models usually merge creation of commercial value with implementation of resource efficiency strategies, such as repair and remanufacturing, by benefit from the economic and environmental value incorporated in products (Bakker et al. 2014; Bocken et al. 2016). According to Nußholz (2017) many of the business models are designed and developed to fit the linear system, in which the environment negative externalities are not integrated in resource prices.

In summary circular business model could be understood as a sustainable kind of BM that tends to become more prominent, due to the challenges to save natural resources and reduce environmental impacts to control climate changes and at the same time improve quality of social and positive social impacts globally.

Summary

Is difficult to offer a single sustainable business model definition since the concept of business model still presents great discussion and perspectives. Even the concept of sustainable development does not imply a particular subject, but preferably a process where ecological, economic,

and social values are balanced in nonstop action. Justifying its definition in a set of components in an integrated and related approach offers value creation to the market, seeking the fair financial revenue we may observe that a sustainable business model implies inter-organizational networks and large societal systems. These networks do not only include companies, but also other stakeholders. Based on these understandings the elements (four) of a business model are presented: value proposition, supply chain, customer interface, and financial model. They are recognized as a set of essential normative requests that are needed to be met for successfully marketing sustainable innovations.

Definition

Although the literature on business model, business model innovation, and sustainable business model innovation have increased in the last decade, it may be considered that the classification and conceptualization of sustainable business model innovation is still in its infancy (Lüdeke-Freund and Dembek 2017). In the literature, the concept of business model innovation is used instead of the existing traditional business model concept, considering the role of innovation in gaining competitive advantage (Adams et al.

2016). Changing environmental conditions and increasing social and environmental awareness have enabled firms to pursue greener practices and put sustainability at the center of their strategies (Bocken et al. 2014). The importance of creating value with the triple bottom line approach put forward by Elkington (2013) has led firms to attach importance to sustainability along with business model innovation, and the emergence of the sustainable business model innovation field and the transformation of the business model. Thus, sustainable business model innovation, in its simplest sense, refers to the changes at the core of business model innovation, which is considered as a key element of the success of an organization, under the rising global sustainability pressures. Sustainable business model innovation highlights the need for innovation in designing a business model and embraces the integration of the ambition of social and environmental objectives besides the economic outcomes into business model innovations.

The Development of Sustainable Business Model Innovation

Business models and business model innovation have received substantial attention both from literature and business. Recently, business model innovations have welcomed sustainability concerns into their agenda. Under these circumstances, to understand the extent of the concept of sustainable business model innovation, a closer look at what a business model is and what a business model innovation means leads to discovering the recent changes and the evolution of the business model to sustainable business model innovation.

Business Model

Business models, which have an important and powerful role for corporate governance, are on the agenda of both the academic world and business life in the twentieth century in terms of what it is and how it will be used.

The business model, which presents a new perspective in the field of management, addresses

the way firms do business with a holistic perspective (Fang 2013; Zott et al. 2010). It basically has the feature of being a guideline, therefore it is a guide for the strategies to be implemented through organizational structures, processes, and systems (Osterwalder and Pigneur 2010). It explains how firms can create value for their stakeholders and differentiate themselves from their competitors in an intensely competitive environment (Fang 2013; Osterwalder and Pigneur 2010). The most important reason why the business model is a strategic positioning (Yip 2004) is that it enables firms to gain value through their innovations and improvements (Ambrož and Omerzel 2017; Chesbrough and Rosenbloom 2002).

In the literature, the business model has been tried to be explained with various dimensions in different studies, and it has been tried to be understood both in theory and in practice. While Shafer et al. (2005) consider the business model dimensions as strategic choices, value network, value creation, and value capture, Johnson et al. (2008), in their four-dimensional model, handled dimensions as the consumer's value proposition, profit formula, key resources, and key activities, emphasizing the importance of cooperation between these dimensions and creating value. On the other hand, Osterwalder and Pigneur (2010)'s Canvas business model consists of nine dimensions, and these are customer segments, value propositions, channels, customer relationships, revenue streams, key resources, key activities, key partnerships, and cost structure. The business model requires a firm to describe the activities and method of doing business that sustains its existence, and to define its position in the value chain and to explain in detail how it profits (Osterwalder et al. 2005). From this perspective, the functions of the business model gain importance and help to implement the business model and to determine the financial capital needed in this process. Furthermore, Chesbrough and Rosenbloom (2002) discuss the functions of a business model. Accordingly, a business model exploits value proposition, market segment identification, value chain structure definition, repositioning the firm within the value network, and competitive corporate strategy formulation.

Business Model Innovation

Especially in times of fierce instability, business model innovation has a critical importance for firms. In fierce competition environments that require continuous innovation, where innovations can be easily imitated and where it is difficult to maintain a sustainable competitive advantage, this competitive environment can be the way out. In its most basic definition, business model innovation is the innovation carried out on the business model to innovate instead of product innovation. In this process, to create a new business model, the basic components of the business model are re-evaluated and new value propositions, revenue streams, and cost structures are created. Business model innovation is believed to provide more competitive advantage when compared to product and service innovations (Chesbrough and Appleyard 2007). Radical changes in business processes to gain competitive advantage or ensure the survival of firms are called business model innovation (Linder and Cantrell 2000).

Implementing business model innovation, which is about creating new value, is a difficult and complex process for firms. Since the definition of Schumpeter, which is accepted as the beginning of the development process of the concept of innovation, it has been shaped by emphasizing its different features. Innovation can be considered as the most effective way of differentiation known today. Differentiation is possible with the existence of hard-to-imitate capabilities of firms (Barney 1991). From the point of view of a resource-oriented approach, developing capabilities suitable for firms' resources and integrating these capabilities with their strategies will provide firms with a competitive advantage in the competitive environment in the market. Business model innovation is also an important capability for firms, and successful business model innovation capability can increase an organization's resilience to changes in its environment and create a sustainable competitive advantage (Mitchell and Coles 2003; Geissdoerfer et al. 2018).

Business model innovation is a systematic procedural activity that enables the firm to gain a new position in the market with new customers and to offer new value to existing customers (Ambrož

and Omerzel 2017). Lingardt et al. (2009) emphasize the necessity of presenting the new value created in a business model innovation to customers in a new way, also they state that two or more components of the existing business model must be changed in order to be able to talk about a business model innovation. Business model innovation, which is not just about innovation, is about the value that innovation creates for firms and enables the firm to increase customer value and gain competitive advantage (Matzler et al. 2013). The most important stakeholder that determines the new value created is the customers, and they reveal the reality of new value with their purchasing behavior. Therefore, the value created by innovation beyond product and technology innovation reveals business model innovation for the firm (Sawhney et al. 2006).

Sustainable Business Model Innovation

As a rule of thumb, the primary condition for a firm's survival is its ability to create economic value. It is possible to carry out all activities, whether in the long or the short term, with the existence and permanence of the resources that enable it to carry out its activities. A business model created by keeping away from the environmental damages brought about by economic growth will contribute to the sustainable goals of the firm. A sustainable business model is related to the firm's resources, processes, and practices that it uses while performing its activities, to provide significant positive effects for the natural environment and society or to significantly reduce the negative effects (Bocken et al. 2014; Stubbs and Cocklin 2008; Wells 2013; Lüdeke-Freund et al. 2018). In other words, sustainability of business models is only possible if the contributions of the business model create a noticeable value in social and economic dimensions. In the sustainable business model, obtaining economic value and making profit is only a tool in the sustainability process and firms need to make efforts to achieve social and environmental goals besides the economic benefits (Freeman and Gilbert Jr. 1992; Stubbs and Cocklin 2008). With this aim, developing structural and cultural

capabilities and to cooperate with the key stakeholders of the system (Stubbs and Cocklin 2008) is necessary for the firms that want to adopt a sustainable business model.

The basic idea of sustainable business model innovation, which starts from the traditional business model innovation but is a much more comprehensive model, can be expressed as revealing the contribution of the business model to sustainability by creating value at the environmental and social level. It aims to introduce a new model by combining the sustainability and innovation ability of the firm and to reveal the environmental and social value creation potential of the firm through this model. With this purpose, strategy and sustainability are the main concepts that are considered as a whole and that are strengthened together.

Summary

Despite the increasing environmental awareness and the changing demands and needs of the consumers, the commitment to sustainability at the organizational level is not yet at a high degree (Kiron et al. 2013). Sustainable business model innovation, which has emerged as a new dimension of business model innovation, includes the belief that sustainability efforts cannot be realized without innovation (Aghion et al. 2009; Shakeel et al. 2020). This understanding necessitated the redesign and improvement of the business models of the sustainable product/service/process innovations (Boons and Lüdeke-Freund 2013; Schaltegger et al. 2012) and this requirement revealed that the elements of business model innovation should be integrated with sustainability. Therefore, sustainable business model innovation defines the processes in which business models are developed and firms transform their current business model goals for sustainable development (Roome and Louche 2016). It is considered as a tool that contributes to the social and environmental conditions through providing solutions to existing problems and that can mitigate the adverse impacts of the industrialization (Bocken

et al. 2014; Evans et al. 2017). Sustainable business model innovation emerges as an area that attracts the attention of today's business world and the academic environment, revealing the potential for sustainable business development and guiding firms to show their talents in this direction (Lüdeke-Freund and Dembek 2017).

Definition/Description

The relationship between companies and sustainability is a critical issue in both developed and developing countries. The private sector has come to realize that long-term profitability depends at least to some degree on social justice and environmental protection. As a result, business objectives and values have changed, as well as the business solutions through which they are implemented. The triple bottom line is no longer a marginal concept but central to the management of the business. “Sustainable business solutions” are those decisions, models, and strategies adopted by corporations or for-profit organizations that positively affect their relationships with one or more stakeholders – including customers, suppliers, employees, and communities – by simultaneously delivering economic, social, and environmental benefits (triple bottom line). Sustainable business solutions, which can increase profitability, are constantly evolving. Multiple sustainable business solutions have been proposed and adopted. They include multi-stage strategies, eco-efficiency models, inclusive business ventures, circular production and manufacturing processes, and solutions addressing overproduction and overconsumption.

Introduction

Traditionally, businesses have implemented economically efficient solutions in the provision of goods and services to seek profit maximization. This type of solution is a fundamental part of capitalism, the world’s dominant economic model (Hart and Milstein 1993). The traditional idea of national development is also associated with market-based development. The underlying theory is that a society is developed if it is modernized and “[t]o be modernized, a society has to become more technically sophisticated and urbanized and to make increased use of markets for the distribution of economic goods and services” (Baker 2006).

The unintended negative social and environmental impact of businesses, however, has led questions about the viability and sustainability of

traditional business models (Wells 2004). Fields and Atiku explain that “[t]raditional business and management practices have been blamed for the crises of the planet specifically. Issues like ecological overshoot, population growth, water and food shortages, financial crises, greed and corruption, as well as greater expectations of shareholders are ... causing the rethink and transformation of business practices and other unsustainable human activity” (Fields and Atiku 2019). As a result, the relationship between businesses and sustainability has become a focus of discussion in both developed and developing countries (Wells 2004).

The private sector has come to accept that business decisions have a broad and more profound impact. An increasing number of companies have realized that long-term profitability now depends on social justice and environmental protection (Fields and Atiku 2019). Especially after the 2007–2008 global financial crisis and the creation of the Sustainable Development Goals (SDGs) by the United Nations (UN), businesses have developed solutions with broader values including social, economic, and environmental agendas in corporate decision-making process (Scheyvens et al. 2016). The UN Global Compact, a UN initiative to achieve sustainable development, explains that an ever-expanding group of enterprises now “recognize that what is good for societies and the planet is also good for business over the long term” (UN Global Compact 2014). Value, therefore, has been redefined. Before, the only value pursued by businesses was economic. Now, companies aim to create social and environmental value for their stakeholders apart from financial success.

It has been recognized that businesses have an important role in sustainable development in general and the SDGs in particular (Mio et al. 2020; UN Global Compact 2014; Van Zanten and Van Tulder 2018). Businesses are central actors in achieving these goals (Mio et al. 2020) and engines for economic growth and sustainable development (Bonnell and Veglio 2011).

Consequently, business objectives have changed. They are no longer purely economic and market-based. Businesses are also social institutions and, as such, they are not independent of society in general

(Wells 2004). For sustainable businesses, social and environmental considerations play an essential role in corporate decision-making. As a result, the business solutions used to implement these objectives have also had to change. These solutions take account of those economic, social, and environmental issues associated with the company’s business-as-usual.

“Sustainable Solutions”

Defining the concept and scope of the expression “sustainable business solutions” requires understanding the concept of “sustainable solutions.”

The concept of “sustainable solutions” is associated with the idea of “sustainable development,” which refers to public policy that encompasses economic, social, and environmental goals (Baker 2006; Sheehy and Farneti 2021). The most critical component of both “sustainable development” and “sustainable solutions” is the achievement of the triple bottom line: economic, social, and environmental objectives (Hart and Milstein 1993).

Therefore, a “sustainable solution” is “one that is long-lasting and resilient, environmentally responsible, economically feasible and socially acceptable” (Wong et al. 2020). The development of sustainable solutions, thus, requires balancing the three dimensions of sustainability, that is, the triple bottom line (Fiksel et al. 2014).

Sustainable Business Solutions

Businesses, governments, NGOs, nonprofit organizations, and civil society must move toward sustainable development (Mio et al. 2020). “Sustainable business solutions,” thus, refer to the strategies and actions that businesses adopt toward sustainable development.

Accordingly, “sustainable business solutions” are “sustainable solutions” implemented by businesses. This concept refers to the way companies do business (Bonnell and Veglio 2011). Particularly, “sustainable business solutions” are decisions, models, and strategies adopted by businesses –

corporations or for-profit organizations – seeking the achievement of the triple bottom line, that is, solutions that are economically, socially, and environmentally viable (Elkington 2006; McCormick et al. 2016; Scheyvens et al. 2016; Wells 2004). The triple bottom line is no longer marginal but central to the business (Wells 2004). As a result, environmental and social issues are no longer ex post regulatory requirements but ex ante business priorities.

“Sustainable business solutions” are also closely linked to stakeholder theory. “Stakeholder theory posits that the integration of economic, ethical, social and environmental issues is a joint aspect of the decision-making process regarding corporate strategic management” (Devalle et al. 2020). This integration in the decision-making process is necessary because businesses are constituted by multiple relationships between different business stakeholders (Freeman 2010). According to Freeman, “[b]usiness is about how customers, suppliers, employees, financiers (stockholders, bondholders, banks, etc.), communities and managers interact and create value” (Freeman 2010). Consequently, the best business solutions create as much value as possible for all stakeholders (Freeman 2010).

To sum up, “sustainable business solutions” are those decisions, models, and strategies adopted by corporations or for-profit organizations that positively affect their relationships with one or more stakeholders – including customers, suppliers, employees, and communities – by simultaneously delivering economic, social, and environmental benefits.

Examples of Sustainable Business Solutions

Sustainable business solutions are constantly evolving. The more awareness and technological innovation exists, the more sustainable solutions companies will offer. Hart explains that “[w]hereas yesterday's businesses were often oblivious to their negative impact on the environment and today's responsible businesses strive for zero

impact, tomorrow's businesses must learn to make a positive impact. Increasingly, companies will be selling solutions to the world's environmental problems” (Hart 1997).

“Sustainable business solutions” also represent business opportunities. They are no longer seen as a burden on businesses but an opportunity to increase profitability while seeking social and environmental benefits. According to Fiksel et al., “[i]n the last few decades, the business community has come to recognize that environmental and social responsibility can actually reduce costs and increase competitiveness, so that today sustainability is widely embraced as a strategic imperative” (Fiksel et al. 2014).

Multiple sustainable business solutions have been proposed. For instance, Hart argues that businesses can achieve sustainable development when they adopt a three-stage strategy. These stages are pollution prevention, product stewardship, and clean technology (Hart 1997). In the first step, businesses must shift from pollution control – cleaning up waste – to pollution prevention, minimizing or eliminating waste. The second step requires minimizing the environmental impacts of the whole life cycle of a product. Finally, Hart explains that businesses must develop sustainable technology to supply goods and services (Hart 1997). Solutions that adopt this strategy can be categorized as sustainable business solutions.

Saling et al. explain the concept of eco-efficiency, a sustainable business solution focused on business productivity that has been encouraged by the World Business Council for Sustainable Development (WBCSD) since 1993 (Saling et al. 2002). Eco-efficiency aims to provide more economic value while reducing environmental impact. It refers to “the ecological optimization of overall systems while not disregarding economic factors” (Saling et al. 2002).

Bonnell and Veglio develop another application of sustainable business solutions. Drawing on the ideas of the WBCSD, they discuss the concept of inclusive business models/ventures. These business models focus on the inclusion and diversification of human capital. Stated differently, they are “sustainable business solutions that expand access

to goods, services, and livelihood opportunities for low-income communities in commercially viable ways” (Bonnell and Veglio 2011).

Diaz-Granados describes an example of sustainable business solutions in manufacturing processes: “cradle to cradle” (C2C). Diaz-Granados explains that C2C is an “alternative approach that “waste” produced by industrial manufacturing processes can be used in a new manufacturing cycle without degrading or downcycling the materials used in the process but rather improving the whole cycle” (Diaz-Granados 2021). Other examples of alternative business solutions based on circular flows of products and materials can be found in sharing platforms and models for reselling, renting, and leasing products (McCormick et al. 2016).

Finally, Bocken et al. provide an example of two companies that apply sustainable business solutions (Bocken et al. 2016). These companies are Fairphone, which has created a phone that can be easily disassembled and repaired, and Patagonia, which implemented a “Don’t Buy This Jacket” advertisement to encourage people to buy only what they need. With these two solutions, Fairphone and Patagonia have attempted to address overproduction and overconsumption of their own products. Bocken et al. note that positive impacts of these solutions may include “the reduction in the consumption of resources, sustainable living and long-term customer loyalty, and new repair and service markets,” as well as “premium margins on high-quality products and high levels of customer loyalty” for businesses (Bocken et al. 2016).

Sustainable business solutions, Elkington argues, require strong corporate governance. “The better the system of corporate governance, the greater the chance that we can build towards genuinely sustainable capitalism” (Elkington 2006). According to Elkington, an increasing proportion of business sustainability issues are associated with corporate design. As a result, a clear corporate governance system where boards are held accountable for the sustainable corporate agenda is a critical step in achieving the triple bottom line (Elkington 2006).

Summary

The negative social and environmental impact of businesses has led to questioning the viability of traditional business models. As a result, the relationship between companies and sustainability has become a critical focal point for discussion in developed and developing countries. The private sector has realized that long-term profitability depends on social justice and environmental protection. Therefore, business objectives and values have changed, as well as the business solutions through which they are implemented. The triple bottom line is no longer marginal but central to the business.

“Sustainable business solutions” are those decisions, models, and strategies adopted by corporations or for-profit organizations that positively affect their relationships with one or more stakeholders – including customers, suppliers, employees, and communities – by simultaneously delivering economic, social, and environmental benefits.

Sustainable business solutions, which can increase profitability, are constantly evolving. Multiple sustainable business solutions have been proposed and adopted. They include multi-stage strategies, eco-efficiency models, inclusive business ventures, circular production and manufacturing processes, and solutions to address overproduction and overconsumption.

Description of Sustainable Chain Management

Recently, the notion of supply chains has expanded with the perspective of sustainability, and it is assumed that organizations should focus on not only financial returns and economic interests of the business but also the social and environmental concerns (Esty and Winston 2009; Gupta and Benson 2011; Kleindorfer et al. 2005). Thus, supply chain management has evolved beyond pure economic concerns due to the rising transparency and customer awareness of where, with whom, with what kind of impacts to the environment, and under what kind of working conditions the production process is arranged. Therefore, supply chain management research

has started to focus on the matters of environment, working conditions, labor rights, and responsible value creation for the stakeholders. By the way, sustainability, which refers to a holistic perspective of integrating social issues, environmental concerns, and economic responsibilities, has started to be considered in organizational operations and has gained an increasing deal of interest by researchers in the field of business management (Carter and Rogers 2008). Sustainable chain management, in its simplest sense, refers to either a new paradigm or a development in the chain management through integrating critical indicators of sustainability performance measurement into supply chain processes and operations. Based on this, both business professionals and academicians have recognized the integration of environmental and social issues into the logistics and supply chain operations. By the way, recently, supply chains are required to be socially and environmentally responsible to their stakeholders.

The Development of Sustainable Supply Chain Management

Following the emergence of the stakeholder theory by Freeman (1984), since the 1990s, companies have realized the significance of their stakeholders and have started to organize their relations with their suppliers, which have an important place among all stakeholder groups, from the perspective of supply chain management. In the most general sense, the supply chain covers the information flows and activities in the process from raw material to the final consumer.

Council of Supply Chain Management Professionals (CSCMP) states that supply chain management involves all planning and management activities of the organizations during the whole process of sourcing, procurement, and logistics. In addition, it also encompasses the conversion, coordination, and collaboration among suppliers, focal companies, and customers. Thus, it is expressed that “supply chain management integrates supply and demand management within and across companies” (CSCMP 2022).

Due to the increasing competition conditions, the effects of globalization, and the rapid development of technology, the structures within the supply chain have started to become complex and supply chain management strategies have been reshaped by companies (Beamon 1999). As Seuring and Müller (2008) highlight that production processes are generally disintegrated and have different stages at different places in the world. However, suppliers, customers, intermediaries, third-party service providers are always in contact and connected with both material and capital flows. Since the beginning of the 2000s, increasing concerns and developing awareness about the social effects of the activities of companies on the environment and society have revealed the necessity of considering the supply chain from a new perspective (Taticchi et al. 2013). To satisfy the customer’s changing demands and needs with environmental awareness, companies have chosen to manage their supply chains effectively with a sustainability perspective, paying attention to the correct and fair use of natural resources (Vachon and Klassen 2006). Meanwhile, if companies on the supply chain are environmentally and socially responsible, the value of the product increases or decreases in the opposite case. For instance, some of the apparel giants such as Nike, Levi Strauss, Benetton, Adidas, or C&A have been blamed for several claims including problems occurring during the production process such as inhumane or working conditions, employing child workers or contamination of the local environment in recent years. As a result, organizations have become more willing to integrate environmental and social matters into their operations and activities, and follow required standards (i.e., ISO standards or GRI guidelines) in daily routines. Under these circumstances, sustainable supply chain management, which can be used as green or environmental supply chain management interchangeably, has gained an increasing interest (Seuring and Müller 2008).

Sustainable supply chain management refers to the management of supply chain operations and resources in order to obtain economic value as well as to minimize environmental impacts and increase social welfare (Taticchi et al. 2013). It

presents a holistic approach of the combination of supply chain management and sustainable development (Esfahbodi et al. 2016). Moreover, sustainable supply chain management encompasses corporate social responsibility, environmental management, and supply chain management simultaneously. This perspective also supports the thesis of supply chain management, put forward by Vachon and Mao (2008), to be positively related to the economic, environmental, and social dimensions of sustainable development.

In the United Nations (UN) Global Compact 2010 Report, where the importance of sustainable development is emphasized, sustainable supply chain management refers to the promotion of governance activities to be implemented throughout the product life cycle of goods and services that can be demonstrated by the management of environmental, social, and economic impacts (UN 2010). For a company that puts sustainability at the center of its strategies, integrating these principles into the supply chain by complying with the principles of the UN Global Compact will enable it to support sustainable development goals and create economic, environmental, and social value in the long run.

According to literature, the stages of greening a supply chain process in design, production, and waste minimization bring together important areas such as environmental risk management, product safety, occupational health and safety, pollution prevention, product life cycle management, resource protection, and waste management (Srivastava 2007). Implementing green sustainable supply chain activities enables companies within the supply chain to better integrate their different activities, thereby increasing efficiency, lowering costs, better managing risks and thus operational efficiency is improved for companies (Gupta and Benson 2011).

Carter and Rogers (2008) describe the economic results of sustainable supply chain activities from five main points: (1) cost savings as a result of reducing waste expenditures, (2) reducing health and safety costs and lowering recruitment and turnover costs as a result of improved working conditions, (3) increasing motivation and productivity, as a result of better working conditions and

dealing with environmental and social problems through a proactive approach to gain competitive advantage, (4) increasing product quality through implementing social and environmental management systems (i.e., ISO 14000, SA 8000), and (5) increasing the corporate reputation, which often has a greater impact on financial performance, and making the company more attractive to all its stakeholders.

Summary

Due to the importance and impact of supply chain management in the activities and sustainability practices of companies, the value created by sustainability policies through the supply chain has become essential today. Sustainable supply chain management ensures communication coordination among suppliers, considering the economic, environmental, and social dimensions of sustainable development of companies throughout the supply chain. The expectation of the company that implements sustainable supply chain management is to keep its suppliers in this chain, to comply with environmental and social criteria, to meet the expectations and needs of customers, to achieve economic targets, and to maintain its competitive advantage (Seuring and Müller 2008). From this perspective, companies are responsible to environmental, social, and economic consequences of their own and their suppliers' operations (Koberg and Longoni 2019).

Sustainable Change Management

► Managing Change for Sustainability

Sustainable City Branding

Jane Croad¹ and Adebimpe Lincoln²

¹Centre for towns and Cities think tank, Robert Kennedy College, Zurich, Switzerland

²Law School, University of Liverpool, Liverpool, UK

Synonyms

Environmental city branding; Environmental place marketing; Sustainable place marketing

Definition

Sustainable City Branding is the management of a city's reputation to reflect the city's achievements and ambitions in environmental, social, and economic development. Sustainable City Branding focuses on the citizens' attaining a sustainable, good quality of life based on United Nations Sustainable Development Goals SDGs, U.N. (2015).

Place and city branding developed as a result of increasing competition between cities to attract tourist, visitors, investors, and residents and is heavily biased toward economic development. Sustainable City Branding reflects city policy that adopts a balanced approach between economic, social, and environmental policies to attract and retain citizens.

Sustainable City Branding is increasingly influential in urban governance putting citizens at the centre of policy-making decisions to improve the well-being of the citizens and enhances the reputation of the city. Adoption of Sustainable City Branding demonstrates a recognition by policy makers of the importance of the city's inhabitants experiencing a sustainable, good quality of life that generates loyalty and commitment from citizens and enhances the reputation of the city.

Over half the world's population live in cities. People are attracted to cities to access employment, social life, good infrastructure, culture, and a good quality of life (Croad, 2020). Cities

can not only improve resource efficiency and contribute to sustainability, but can also lead to pollution of air and water and other negative factors. Part of the Sustainable City Branding process is to constantly monitor factors of urban living to inform city policy and to achieve a sustainable high quality of life.

Introduction

In the twenty-first century, Sustainable City Branding has developed due to the increasing awareness of environmental issues and access to technology. It is an amalgamation of disciplines including Tourism Management, Natural Sciences, Urban Studies, and Marketing (Morgan et al. 2011). In the 1970s, place promotion based in Tourism Management was used to attract tourists to locations, later in the 1980s and 1990s as neoliberalism influence moved local governance from a managerial role to an entrepreneurial role, urban policy making adopted city marketing to attract skilled workers, investment and visitors, focusing on economic growth (Eisenschütz, 2010). Also, in the 1980s, the Brundtland Report called for a conciliation of economic efficiency, equity, and environmental protection. The Earth Summit in Rio made local governments responsible for “sustainable development” initiatives (Mancebo & Sachs, 2015).

Accessibility to technology via mobile devices and the use of social media platforms has increased the voice of citizens and given citizens an increasing ability to communicate among each other, to mount campaigns and to make their expectations known to local and national policy makers. Citizens can make their approval or discontent with city policy clear and can urge others into action. The obligation for urban governance to embrace the requirements of the citizens has become central to policy making, locally and nationally. Increased support for environmental protection issues and the drive towards zero carbon from mainstream, apolitical citizens has focused policy makers more toward the benefits of sustainability in city policy making which is communicated through Sustainable City

Branding to demonstrate how the priorities of citizens are being acknowledged and fulfilled (Arcanjo, 2020).

According to Schaefer et al. (2015), the Organisation for Economic Co-operation and Development (OECD) identified that sustainability depends on developing economic growth and social development while ensuring that natural assets are protected and maintained. It further established that environmental policies are not sustainable in the long term without economic growth and wealth creation. Developing Sustainable City Branding to effectively manage the city’s reputation regarding the sustainable development of the city is the key to effective urban development and to relevant, effective policy making that addresses the sustainable quality of life expectations of the city’s citizens.

Key Issues

Sustainability City Branding is predicated on effective monitoring and communication. To achieve credible Sustainable City Branding the image and reputation needs to accurately reflect the achievement of satisfaction of the citizens and other stakeholders with the environmental, social and economic development of the city.. Through monitoring of the environmental, social and economic developments in achieving sustainability goals and maintaining interactive communication with citizens to evaluate the quality of life and well-being standards achieved through sustainability. Effective, accurate Sustainable City Brand will make the city attractive to visitors and investors (Fig. 1).

The Sustainable City Branding Cycle (Croad, 2020) is the interconnection between sustainability policy, stakeholders and the monitoring, communication role of Sustainable City Branding to provide good quality of life through balanced development of environment, social, and economic elements.

Environmental

Sustainable City Branding’s focus for monitoring environmental issues in the city include clean and safe water to drink and for other uses such as washing; clean air and efficient waste disposal

Sustainable City Branding, Fig. 1 The Sustainable City Branding monitoring and communication cycle. (Croad, 2020)

preventing contamination of water resources such as rivers, streams, lakes, and seas. Energy efficiency and availability of green spaces are also important components on the many environmental issues that Sustainable City Branding needs to monitor and feedback into urban policy making.

Clean air is important to stakeholder's health, and to maintaining clean and attractive buildings and monuments. Air quality management plans are needed to tackle air pollution from traffic, domestic heating, and local industry.

Sustainable City Branding policy will require effective policies for management of waste; including management of collection and disposal of solid waste through composting, recycling, and incineration with energy recovery will be developed and implemented with landfill only used as a last resort. Policies will include stakeholder's involvement to encourage, engage, and involve stakeholders to minimize, reuse, and recycle waste and to contribute to innovations to address the growing problem of waste disposal in cities.

Sustainable City Branding will include policies for green spaces, recreational areas for the health and well-being of citizens, fostering biodiversity, and protecting habitats. It also ensures no harmful use of pesticides in areas used by people such as playgrounds, parks and sports facilities.

It is important for Sustainable City Branding that the city functions efficiently and minimizes the use of natural resources. This includes avoiding city sprawl and maximizing the land use in cities by the development of brown field sites. Energy efficiency is key to Sustainability City Branding adopting the development of energy-efficient buildings that require less energy for lighting, heating, and cooling.

Efficient city infrastructure and transport, through an effective Sustainable Urban Transport Plan, is key to stakeholder's quality of life and to economic development and an important part of Sustainable City Branding. The reduction of emissions from internal combustion engines, through increased use of public transport using nonfossil

fuels, walking and cycling are positive contributors to achieving positive environmental outcomes and will be part of the city's contribution to reduce greenhouse gas emissions. An effective digital infrastructure will enable effective communication and involvement whilst minimising the carbon footprint.

Economic Factors

The economic focus for Sustainable City Branding includes support for employment in the knowledge economy through education and training, establishing Eco-innovation and sustainable employment initiatives to improve sustainability and develop policies to support and encourage technological innovation and creativity to ensure the sustainable future of cities. Specifically, there is a need to invest in green technologies to realize economic returns as has been achieved in cities such as Hamburg. Programmes are needed to integrate science and technology into all cities.

Policy focus on environmental technology projects to address other environmental problems associated with the generation of waste in cities is needed, providing support to create green jobs at all levels of skill and experience and to support enterprises in new technologies. Green public procurement is another policy to be considered in Sustainable City Branding; procurement activities should consider environmental implications along with other considerations to reward environmental endeavors of suppliers. Policy strategies for encouraging technological eco-innovation and entrepreneurship in sectors such as renewable energies, biofuels, and investment to developing competitive green technology firms and related industry will be positive contributors to the economic sustainability of the city.

Social Factors

The Sustainable City Branding monitoring focuses on social factors which include improving communication and transparency of policy making for the stakeholders of the city. This includes well-managed and democratically integrated environmental, social, and economic management systems.

As part of the social policy for Sustainable City Branding, events associated with positive ecological orientation can provide positive emotional experiences and improve the lived and perceived quality of life that a city provides. Marin-Aguilar and Vila-López (2014) identify the National Fair of San Marcos in Aguascalientes, Mexico, in 2011 as an environmentally orientated megaevent that contributes to positive social attitudes toward the city and enhances a sense of community and belonging.

Social policy for Sustainable City Branding will benefit from the support and inclusion of urban heritage, based on the city's history, culture, and traditions. This will include the conservation of historical buildings, heritage sites, and traditional festivals which will encourage stakeholders to form emotional and physical attachments to urban heritage and improve social well-being and positive connections to the city.

Future Direction

A key initiative to contributing to the framework on which Sustainable City Branding is developed is the European Green City Award (EGCA) which required cities to satisfy the following conditions:

1. Maintaining high environmental standards.
2. Continually striving toward sustainable development with an emphasis on ambitious environmental goals.
3. Being an inspiration to other cities.

In the application phase, a city needs to demonstrate its results and plans for future years and decades in domains including climate change adaptation, local transport, green urban areas, nature and biodiversity, noise pollution, waste production and management, water management, and so on (Demaziere, 2020).

Another initiative is the "CittaSlow"; this slow movement is a contributor to sustainability branding policy in some cities aiming to contribute positively to the society by protecting and preserving the traditions, heritage, culture, and natural attributes of the city. This is a reaction to the increased globalization of many cities with global

high street chains taking over the high street and out-of-town retail parks having a deleterious effect on local independent businesses. This may be an appropriate movement for some cities, or even as a part of a sustainable city-branding strategy (Doyduk & Okan, 2017).

There are some examples of cities that have successfully adopted Sustainable City Branding such as Sweden which has developed a holistic approach to sustainable development and Sustainable City Branding. It is acknowledged internationally as an exemplar illustration of the sustainable city concept with the functions of waste management, water management, and energy management that are integrated, and the residents are seen as an integral part of the ecological cycle which is central to the city brand (Demaziere, 2020).

Hamburg has also adopted sustainability policies and Sustainable City Branding successfully. It was historically a highly industrialized city and has successfully transitioned to a city that has high standards of environmental performance. Hamburg's Sustainable City Branding has been strengthened by receiving the EGCA in 2011 and is now perceived as a green, sustainable, innovative, and environmentally conscious city (Flämig et al., 2019). Hammarby Sjostad and Hamurg illustrate the successful adoption of key factors of Sustainable City Branding.

Increasingly, Sustainable City Branding strategies use communication within the city to adopt circular economies to reduce waste and encourage recycling, and also encourage exchange cultures that strengthen community involvement and inclusivity. The Covid19 pandemic has supported the Sustainable City Branding focus on buying locally and reducing physical travel while encouraging and developing technology to facilitate virtual global communication using virtual platforms such as Zoom and Teams. This adaptation to virtual methods of communication has been adopted throughout commerce, and by citizens of all age and economic groups, contributing to sustainability through social, environmental, and economic benefits.

Strategies to Foster Sustainable City Branding

Strategies to foster Sustainable City Branding include the following: education – lifelong learning relating to the life enhancing the role of suitability; infrastructure (physical and digital) – facilitating sustainability, employment, and training in sustainable industries; and built environment – supporting heritage and culture while developing energy-efficient aesthetically pleasing built environment. Policy needs to support local businesses and increased community activities to strengthen communities.

Summary

Sustainable City Branding manages the reputation of the city, reflecting a focus on sustainable high-quality life goals. The unsustainable economic focus for city development has been replaced with a drive toward a conciliation of economic, social, and environmental balanced development; the Earth Summit in Rio made local governments responsible for taking “sustainable development” initiatives (Mancebo & Sachs, 2015).

The main challenge of Sustainable City Branding is coordination of urban policies that are coherent and match the requirements for sustainable life in the city. Although there is consensus among most policy makers that improvement of the urban environment is a major objective for sustainability and quality of life, there is a lack of consistency in aims and policy agreement between departments and organizations in the same city as to how to achieve effective sustainability policies and Sustainable City Branding. There needs to be a strong basis of agreement in cities because without clear policies on sustainability and effective operational strategies, progress cannot be made.

Effective coordination and cooperation between policy makers, citizens, and key organizations in cities to achieve sustainability and credible Sustainable City Branding in a city is needed. The Leipzig Charter on Sustainable European

Cities positively contributes to this goal, prioritizing health, esthetics, and sustainability in cities (Environment Directorate-General European Commission, 2010).

Environment Directorate-General European Commission (2010) contributes to the framework for effective policy making for Sustainable City Branding with focus on supporting sustainable local communities, effective infrastructure, increased use of renewable energy, and energy efficiency. Sustainable high-quality urban development will attract inward investment and economic growth. Equity issues need to be included in sustainability policies in cities and promoted in Sustainable City Branding to ensure diversity and inclusivity in cities to meet criteria for balanced long-term economically, socially, and environmentally successful development in cities.

Definition

There is no single, agreed upon, definition for sustainable community simply because both the terms therein are open to a myriad of interpretations. Despite this, there have been several attempts in this context.

Community can be understood as a diverse social group which shares, among others, values, beliefs, perspectives, and/or identity.

Sustainable on the other hand is understood as the ability to consistently maintain and/or carry forward at a given level. In this vein, sustainable also means using our (natural) resources in a way so as to not burden the future generations. This would thus include the SEE factors, i.e., social, environmental and economic factors.

Sustainable community could be therefore defined as a community with the shared idea and purpose of making efficient and effective use of (natural) resources to meet the social, environmental, and economic needs of the present and future inhabitants of the community.

According to Egan (2004) “Sustainable communities meet the diverse needs of existing and future residents, their children and other users, contribute to a high quality of life and provide opportunity and choice. They achieve this in ways that make effective use of natural resources, enhance the environment, promote social cohesion and inclusion and strengthen economic prosperity” (p. 7).

To achieve a sustainable community, several different and necessary aspects need to be brought together. Egan (2004) states these aspects are governance, transport and connectivity, services, environment, equity (fairness), economy, housing and built environment, and finally social and cultural aspects. Egan’s wheel is an often referred to benchmark in this context.

In other words, sustainable communities are places where people want to live and work, not just for now but also in future.

Background

History has shown that many civilizations have collapsed due to shortsighted policies on protecting our delicate ecosystems and stemming of population growth.

With no change in mortality and fertility, the world population is projected to grow to 10.1bln according to UN (2019). To sustain this level of population, the need for resources is going to multiply many times. OECD (2018) projects use

of resources such as metals, fossil fuels, biomass, and nonmetallic materials will grow more than twice from 79Gt in 2011 to 167GT in 2060. Since materials and their related activities are responsible for a large part of the greenhouse gas emissions, the resulting environmental damage is likely to be beyond repair (OECD 2018). It is now obvious that the environment is not as resilient and self-healing as previously believed.

The awareness created by environmental organizations and interested stakeholders has been accelerated by catastrophic man-made accidents such as the Exxon Valdez Spill (Leahy 2019), Chernobyl (Blakemore 2019), the BP Deepwater Horizon oil spill (Department of Justice 2012), Union Carbide Limited gas leak (Dubey and Khandekar 1984), etc.. This environmental awareness has been also deeply compounded by heightened human and animal rights awareness. Sustainable community, in many ways, is a personal manifestation of a deep-seated desire to achieve a much more conscious way of living.

Attempts at building sustainable communities have been made in the past, but most have been restricted to solving shortage of housing issues rather than achieving a sustainable community (Office of the Deputy Prime Minister 2003). Unlike its general interpretation, sustainable community is not just about decent, affordable housing. Instead, it is about setting up a self-sustaining, thriving, inclusive community working effectively to build an environmentally, socially, and economically sustainable present and future for its diverse population. This includes transportation, housing, food, culture, job opportunities, education, health care, etc. (Egan 2004).

Several (local) governments around the world along with NGOs have developed advisory bodies, guidelines, and practical toolkits to plan cities or city expansions, rural development, create eco-villages, etc. under the premise of sustainable community incorporating necessary and conducive environmental, social, and economical aspects (Penha-Lopes and Henfrey 2019). The long-term benefits of such communities are manifold in terms of preservation of nature, protection

of social norms, upholding of respect and rights, and general well-being.

The dramatic change in pace of life over the past couple of decades punctuated frequently by natural catastrophes, man made and natural crises, have all spurred on the need for building many more such communities.

CSR Context

In pursuit of profits and delivering year on year growth to their various vested stakeholders, companies often cut corners or are forced to do so under the relentless pressure of performance growth. The idea of continuous growth is myth though this does not stop its pursuit. Resources are not endless and typically tend to have a linear growth pattern, while population and its related consumption of resources are exponential (Sherwood et al. 2017). A company whose CSR policies proactively engage with stakeholders with an aim to deliver them their long-term prosperity while not compromising environmental, social and economic aspects could soon see itself become the nucleus of a sustainable community with a healthy, thriving, eco-friendly, inclusive society developing around it.

One way to stem the potential destruction of the planet given our myopic tendencies is to proactively encourage more and more mainstream sustainable communities. In other words, make sustainable community a standard and not just a

perk. A way to encourage development of more and wide-reaching sustainable communities is for companies to be proactively sustainable in the sense of SEE factors.

A company whose CSR policies proactively engage with sustainability with an aim to deliver long-term prosperity to its stakeholders while not compromising environmental, social and economic aspects could soon see itself become the nucleus of a sustainable community with a healthy, thriving, eco-friendly, inclusive society developing around it.

Sustainable Companies

Mara Del Baldo

Synonyms

Community-based companies; Convivial enterprises; Humanistic enterprise; Spirited businesses

Definition

Despite irresponsible behaviors are still diffused, a number of studies have highlighted the emergence of companies that mirror a strong sustainability orientation and are authentically CSR (corporate social responsibility) oriented (Jenkins 2004, 2006; Del Baldo 2017). Even if they represent a diversified universe, these companies can be considered sustainable companies, because they are characterized by the tension toward the multiple dimensions (economic, social, environmental) of sustainable development, are marked by a long-term orientation, and ascribe a fundamental relevance to people (inside and outside the company), relational capital, and the community they belong to.

Sustainable companies integrate sustainable development goals (SDGs) into their business (UN 2015). They are high-performing companies whose competitive success grows out of their commitment to an ethical-led substratum. They embody a humanistic enterprise model, that is a way of doing business that places people at its core, where work is conceived as an expression of human value and profit as a mean to achieving the true good, that is, to improve the lives of workers, customers, suppliers, and, more generally, all stakeholders, included in the environment. Sustainable companies can also be appreciated as “companies with a soul” since they have a specific character, drawn from the principles triggered by the entrepreneurs/managers that are

mirrored in their mission and translated into the governance.

Introduction

Corporate sustainability has been conceived as “meeting the needs of a firm’s direct and indirect stakeholders (such as shareholders, employees, clients, pressure groups, communities), without compromising its ability to meet the needs of future stakeholders as well” (Dyllick and Hockerts 2002, p. 131). Moreover, it has been defined as “companies’ responsibility for their impact on society” (EC 2011). The sustainability model of the Lisbon Treaty and the EU 2020 strategy – described as smart, inclusive, and green growth – rests on activities that include voluntary social and environmental actions, the respect of sustainability standards, transparency and stakeholder engagement, sustainable operations, and relationships culminating in new business models in which sustainability constitutes the core business. Through CSR companies are targeted toward the ultimate goal of sustainability and voluntarily incorporate social, ethical, and environmental concerns in their daily business operations (WCED 1987; Elkington 1994).

Sustainable companies are a manifestation of sustainable entrepreneurship. The latter refers to the discovery, creation, and exploitation of entrepreneurial opportunities that contribute to sustainability by generating social and environmental benefits for the whole society (Osburg 2014). Sustainable entrepreneurship has been widely acknowledged as the answer to environmental and social challenges (Zahra et al. 2009).

Sustainable companies manifest a “conviviality” that is intended as the attitude to improve relationships with stakeholders and the territory/community to which they are embedded because business’ success goes alongside with the surrounding local context (Balloni and Trupia 2005). One of the principle motivations of entrepreneurs/manager who lead sustainable companies is the desire to do something useful for their own community. This is because the histories of their businesses have always been founded

on “passion” rather than mere calculation. Accordingly, they spend their efforts in behaving as responsible citizen and advancing sustainability. Moreover, they feel responsible of best practices by acting as stimulators of partnerships and exchanges among other companies.

Embeddedness is experienced as active participation to the territorial community and represents a distinctive feature of territorial companies (Del Baldo 2012a). A sense of belonging to a specific territorial context is a key driver of the business model and allows the company to nurture responsible networks, based on a shared ethical orientation. Such networks – that comprise internal and external stakeholders (i.e., public and civic institutions, banks, trade associations, unions, local authorities, nonprofit organizations, chambers of commerce, among others) – are social in nature and rest on personal relationships among individuals that allow the exchange of social goods (Niccolini 2008). Therefore, sustainable companies have a narrative identity: they trace a path whose origins derive from the local social capital.

Key Issues

Sustainable companies rest on both tangible and intangible resources that render them dynamic and innovative. The social and the environmental strategy, as well as the involvement of stakeholders, contribute to develop competitive resources. Features such as the culture, history, beliefs, and shared convictions (the so-called *genius loci*) represent the humus of the intangible assets. Sustainable companies aim to use their activity to progress (and make it flourish) the local and global community. Accordingly, they contribute to build a model in which territory becomes the place where sustainable development can be concretely operationalized.

Sustainable companies are not merely intended to generate economic benefits, but as drivers of a “neo-capitalism” that has been defined as “humanistic capitalism.” In this framework the common good is the guiding force and humankind is at the center of production and consumption processes.

Among the core principles of sustainable companies the following embody the features of the humanistic model: respect for the individual, the environment and the territory, and responsibility to society.

First, sustainable companies promote respect for the physical and cultural integrity of individuals and for interpersonal relations. They promote the value of human resources, increasing the wealth and skills of each employee and collaborators. They guarantee working conditions that are respectful of individual dignity and safe working environments.

Second, relationships with stakeholders are driven by cooperation, loyalty, and mutual respect, which consist in acting with a sense of responsibility.

Third, they contribute to environmental sustainability. The commitment to safeguard the environment is put into practice by planning activities that seek a balance between economic and environmental needs over the law.

Finally, they contribute at promoting the economic, social, cultural, and civil growth. Sustainable companies nurture the “dream” to generate social and environmental goods, because they are aware that profit is not enough and a higher purpose is to be found.

As afore mentioned, there is a diversified universe formed by several types of companies that can be considered sustainable companies. Such companies are often driven by an ethical substratum (Hoivik von Weltzien and Melé 2009; Hoivik von Weltzien 2014) and through their activity generate material positive impact on society and the environment. Among the various forms and types are benefit corporations and B corps (Clark et al. 2013; Hiller 2013; Honeyman 2014), società benefit (Castellini et al. 2017; Nigri et al. 2017; Nigri and Del Baldo 2018; Del Baldo 2019), inclusive business (Jenkins et al. 2010; Gradl and Knobloch 2010; Gradl and Jenkins 2011), community-based companies (Peredo and Chrisman 2006), spiritual enterprises (Malloch 2008; Pruzan 2001; Capaldi 2013), territorial companies (Del Baldo 2010, 2012a), economy of communion companies (Del Baldo and Baldarelli 2015), convivial enterprises, and

purpose-driven businesses (Jenkins 2004, 2006; Molteni 2009).

Among the possible types of sustainable companies an emerging model is represented by benefit corporations and B Corps that have been recognized by legislation in the USA and Italy in recent years (B Lab 2016). Their mission differs from shareholder value maximization in that they represent alternative models of enterprise (hybrid organizations) that bridge the for-profit and not-for-profit model (Clark et al. 2013). A benefit corporation is an institutional form with a recognized legal structure. It is for-profit entity that has voluntarily and formally committed to pursue a general or specific public benefit by creating social and environmental outcome, in addition to its responsibility to return profits to the shareholders. Benefit corporations “are required to have a purpose of creating ‘general public benefit’ and are allowed to identify one or more ‘specific public benefit’ purposes” (Clark et al. 2013, p. 17). General public benefit is intended as a material positive impact on society and the environment, as evaluated against the B Lab standard (a not-for-profit third-party standard-setting certifying organization founded in Pennsylvania in 2007) including, among others: providing low-income or underserved individuals or communities with beneficial products/services; going beyond the creation of jobs in the normal course of business; protecting or restoring the environment; improving human health; promoting the arts, sciences, or advancement of knowledge (White 2015).

While a benefit corporation has the obligation to draw up an annual report to assess and communicate its financial, social, and environmental performance, a B-Corp refers to a business of any legal form that has obtained a certification as to its level of responsible business conduct. A B-Corp is subject to a “B Impact Assessment” (BIA) powered by B Lab that evaluates companies across five broad categories: environment, employees, customers, community, and governance.

Further types of sustainable companies are those of SMEs (small and medium-sized enterprises) that are authentically oriented to CSR.

SMEs are often purpose-driven companies (Del Baldo 2012b). In such contexts the owner-entrepreneur forges the company's mission and the business models. The ethical and socially orientation mirror his/her values, attitudes, and behaviors. "To evaluate the conditions on which the firm can cultivate an ethical and collective conscience, one must start from the motivations that inspire entrepreneurial or managerial behaviour" (Sciarelli 2007, p. 110). A growing piece of research, centered on various cases involving SMEs, allowed verifying an important connection between orientation toward sustainability of companies led by entrepreneurs ("champions of CSR") and the sharing of those values typical of their local context (Putnam et al. 1993).

Many companies strive to integrate CSR and sustainability into their core business. Implementing sustainability within the business context means integrating it into the core business and/or reorienting enterprises with the aim of creating sustainability. This implies an authentic and effective sustainability orientation, while "the prevailing approaches to CSR are so disconnected from strategy as to obscure many great opportunities for companies to benefit society" (Porter and Kramer 2011, p. 68).

In this regard a further example of sustainable companies is represented by inclusive business initiatives aimed at creating a corporate shared values. While CSR programs can have a limited connection to the business, inclusive business initiatives are internal to a company's profitability and competitive position and involve collaboration with stakeholders (Porter and Kramer 2011) to discover opportunities that benefit society by strengthening the competitive context in which they operate.

Inclusive businesses support sustainability-oriented projects and actions on national and international levels addressing the issues of poverty, environmental change, among others. In this regard there is increasing interest in local communities, and the operationalization of sustainability at the local level, especially in disadvantaged communities and underdeveloped

countries (Leca and Naccache 2011; Mair and Seelos 2007) where an important role can be played by community-based enterprises capable to promote institutional changes and provide a strategy for sustainable local development (Peredo 2003) when the community acts entrepreneurially. "Community-based-enterprises are managed and governed to pursue the economic and social goals of a community in a manner that is meant to yield sustainable individual and group benefits over the short- and long-term" (Peredo and Chrisman 2006, p. 4). Community-based enterprises are built upon the collective skills and resources of the community, and they have multiple social and economic goals acting corporately in pursuit of the common good. They depend on social capital since they are created on the basis of collectively owned cultural, social, and ethnic endowments.

Future Direction

Sustainable companies aim at spreading a shared and durable prosperity. This goal is impossible to achieve if leaders are oriented toward short-term financial and competitive success, or adopt CSR strategies merely aimed to increase the company's (and their own) legitimacy. In accordance with these lines of thought, sustainable companies need for a coherent leadership model, capable of triggering and stimulating social innovation (Vogel and Fischler-Strasak 2014).

The model of humanistic capitalism centered on sustainable companies (such as benefit corporations, purpose-driven companies, territorial companies, community-based companies) leans on the construction of the common good. Sustainable companies, often less visible than irresponsible ones, consider people, community, and the territory as key resources and should be experienced as common good, because they do not limit themselves to being hidden champions, rather they offer the chance to inspire the institutional and business world in actually implementing sustainability.

Summary

Raising consciousness of social and environmental problems on a global scale requires more awareness for the responsible behavior of companies (Avery and Bergsteiner 2011). The economic growth and wealth creation that are essential to achieve sustainable development goals will come primarily from private enterprise (Nelson and Prescott 2008). In this regard a key role is played by sustainable companies that can assume different forms. Among the diverse possible types, community-based enterprises, as well as territorial company, convivial enterprises, benefit corporations, and B Corp, are all examples of actual declinations of promising models for a sustainable development seeing communal values and the notion of the common good as essential elements (Del Baldo 2014; Jenkins et al. 2010).

Sustainable Competitive Advantage

Definition/Description

“Sustainable competitiveness is the ability to generate and sustain inclusive wealth without diminishing the future capability of sustaining or increasing current wealth levels” (Solability 2022a). Solability has published the Global Sustainable Competitive Index (GSCI) since 2012 (Solability 2022b; Zhongming et al. 2020).

The above cited and generic definition is tangential to the Brundtland Report “Our Common Future” that defines sustainable development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland 1987). Instead of then-existing earlier descriptions mainly focusing on economic aspects, the report combined economic development with social and environmental stability. The above definitions include the economic, social, and environmental dimension.

A commonly cited index to measure competitiveness is the Global Competitiveness Index (GCI) by the World Economic Forum (WEF), that has defined competitiveness as “the set of institutions, policies and factors that determine the level of productivity of a country” (WEF 2011) and sustainable competitiveness as “the set of institutions, policies, and factors which make a nation productive over the long term while ensuring social and environmental sustainability” (WEF 2015).

Sustainable competitiveness relates to both sustainability and competitiveness as well as to several sustainability and competition-related concepts, such as sustainable competitive advantage. However, despite a significant amount of research and literature on sustainability and competitiveness, and a growing amount on sustainable competitiveness, there still is no uniform definition for the term sustainability (Adams et al. 2016), nor competitiveness, nor unambiguous understanding regarding the concepts or measurement methods, nor interpretations of results of such measurements (Balkyte and Tvaronavičienė 2010; Kirjavainen and Saukkonen 2020, Salimova et al. 2018).

What Do We Speak About When We Speak About Sustainable Competitiveness?

Several global organizations and other stakeholders as well as academic scholars have described both sustainability and competitiveness and developed measurement indexes. However, despite the massive amount of research and literature, sustainable competitiveness remains unanimously determined; as well as its underlying terms sustainability (Adams et al. 2016) and competitiveness (Balkyte and Tvaronavičienė 2010; Kirjavainen and Saukkonen 2020, Salimova et al. 2018). In addition, although the number of work and reports is growing, the angle to competitiveness has not been from the globalization and sustainable development point of view (Balkyte and Tvaronavičienė 2010).

Regarding “sustainability” in relation to the term sustainable competitiveness, Solability has defined sustainable competitiveness as sustainable management, with interplay between sustainability and profitability, and as sustained competitiveness, as follows: “Sustainability is not a new concept. It is an evolution of existing management thinking and paradigm. The difference to conventional management is that the horizon on which management decisions are taken is wider in width (issues) and depth (time). Sustainable management therefore is superior to conventional management. Sustainable management is sustainable competitiveness, is the foundation to sustain competitiveness. Sustainability is profitable – and profitability is sustainable” (Solability 2022a).

Regarding “competitiveness,” the term is often approached either from the international (global) level, national (country) level, regional (city or region) level, or organization (firm) level (Balkyte and Tvaronavičienė 2010; Kirjavainen and Saukkonen 2020). Further, the definition of competitiveness can include a narrower time-related dimension (Coyne 1986; Huang et al. 2015; Kirjavainen and Saukkonen 2020).

Several major economic organizations, such as Organization for Economic Co-Operation and

Development (OECD) (Hatzichronoglou, 1996), the World Economic Forum (WEF), and the International Institute for Management Development (MIF) have all created concepts for competitiveness and indexes to measure them. Models from renowned and cited authors such as Porter (1990) have been utilized.

Building upon various definitions based on an in-depth and cited literature review on competitiveness, Balkyte and Tvaronavičienė outline that “Competitiveness is not just about growth or economic performance but should take into consideration the ‘soft factors’ of competitiveness, such as the environment, quality of life, technology, knowledge, etc.” (Balkyte and Tvaronavičienė 2010, p. 344). Thus, “globalization, economic dynamism and social progress, sustainability and competitiveness go hand in hand” (Balkyte and Tvaronavičienė 2010, p. 360) and “the different sets of competitive advantages interact and reinforce each other” (Balkyte and Tvaronavičienė 2010, p. 359).

Accordingly, regarding sustainable competitiveness, Herciu and Ogorean consider the main theme of sustainable competitiveness as a search for a model that would equalize economic prosperity and environmental and social dimensions of sustainability (Herciu and Ogorean 2014). In addition, they note that before adjusting the global competitiveness index to include two then new elements, the environmental and the social, in practice means that also the concept of the triple bottom line (Elkington 1997) will become generalized from the microeconomic standpoint to the macroeconomic level (Herciu and Ogorean 2014).

Regarding competitiveness at the firm level, largely cited Coyne (1986) considers the term “sustainable competitive advantage” from the company competitive advantage point of view, and from a certain time-related economic perspective: “The most important condition for sustainability is that existing and potential competitors either cannot or will not take the action required to close the gap. If the competitors can and will fill the gap, the advantage by definition is not sustainable” (Coyne 1986, p. 58). The aspect of time relating to the competitive advantage can also

occur via perception of the competitive advantage as either “temporary” or “sustainable” (Huang et al. 2015).

Further, approached at the firm level, from the perspective of “an individual economic entity” (Salimova et al. 2018, p. 161) and taken into account that “despite a significant amount of studies on the issue of ensuring the competitiveness of enterprises, there is no unambiguous interpretation of this term” (Salimova et al. 2018, p. 164) as well as building upon literature, they however conclude the “competitiveness as an enterprise” as “the ability to be flexible and adaptive in changing conditions of competition, while maintaining integrity and efficiency of business management” (Salimova et al. 2018, p. 165).

Why Does Sustainable Competitiveness Matter?

First, although no uniform definition for sustainable competitiveness exists, one acknowledged meaning is a competitive advantage, or strategic competitive advantage it brings to its user.

At the firm level, the sustainable competitive advantage means a strategic competitive advantage as an “integrated set of actions that produce a sustainable advantage over competitors” (Coyne 1986).

The closely associated term to sustainable competitiveness is corporate social responsibility (CSR). In the European Commission’s Green Paper promoting a European framework for CRS, it is defined as “a concept through which the company voluntarily integrates the social and environmental dimensions in its business operations and in its relations with stakeholders” (COM 2001 366). CSR is capable of creating value as a competitive advantage (Aggerholm et al. 2011; Du et al. 2010; Carlini et al. 2019; Siegel and Vitaliano 2007). If a firm is imaged as a socially responsible company, the stakeholder engagement is positively impacted (Greening and Turban 2000; Carlini et al. 2019). However, the opposite impact may occur and the company brand may be harmed, if stakeholders perceive the signals of social responsibility as fake signals and the

company as a humbug (Anselmsson et al. 2016; Carlini et al. 2019; Scheidler et al. 2019).

Regarding the closely associated and underpinning term sustainable development illustrated by the Brundtland Report (Brundtland 1987), the European Union converted a strategy for sustainable development (COM 2001 264). Furthermore, the European Union revised their strategy furnishing “a long-term vision for sustainability in which economic growth, social cohesion and environmental protection go hand in hand and are mutually supporting” (European Union 2006). European Union further expressed that there were certain unsustainable trends and in this regard, the requirement for greater efforts to address these issues (European Union 2009). At the same time, the European Commission’s reviews acknowledged the progress within the European Union to promote sustainable development via many policies. Also, it noticed the European Union’s attempts to head the development in the fields of advancing a low-carbon economy and address the climate change. Today, sustainable development is among the European Union’s long-term targets (Article 3(3) of the Treaty on European Union).

Earlier, through the United Nation’s conference in Rio de Janeiro in 1992, the nations agreed that the economic growth and environmental sustainability should ally (Weiss 1993).

In addition to sustainable competitive advantage and CSR, a further closely associated term is strategic corporate social responsibility. It has been described as “any ‘responsible’ activity that allows a firm to achieve a sustainable competitive advantage, regardless of motive” where strategic corporate responsibility creates sustainable competitiveness to a company (McWilliams and Siegel 2011).

How to Measure Sustainable Competitiveness?

This question has started to interest scholars since the 1980s. Although no unanimous method to measure sustainable competitiveness yet exists (Balkyte and Tvaronavičienė 2010; Popescu

et al. 2017; Salimova et al. 2018), attempts to measure it have been carried out by organizations and stakeholders, approaching the theme from various viewpoints.

Regarding the international (global) ranking level, the index directly originating in the term sustainable competitiveness is the global sustainable competitiveness index (GSCI). It has been published by Solability since 2012 (Solability 2022b; Zhongming et al. 2020) and has gained academic attention (Doyle and Perez-Alaniz 2017; Herciu and Ogorean 2014; Rosati and Faria 2019). GSCI measures sustainable competitiveness as “competitiveness of countries based on 189 measurable, *quantitative* indicators derived from reliable sources, such as the World Bank, the IMF, and various UN agencies. The 189 indicators are grouped into 6 sub-indexes: Natural Capital, Resource Efficiency & Intensity, Social Cohesion, Intellectual Capital, Economic Sustainability, and Governance Efficiency” (Solability 2022b). According to them, “it is the most comprehensive ranking of countries currently available” (Solability 2022b).

Regarding the international (global level), a renowned and commonly cited index linked to competitiveness is the global competitiveness index (GCI). It has been published via the Global Competitiveness Reports by World Economic Forum (WEF). The WEF definition for competitiveness is “the set of institutions, policies and factors that determine the level of productivity of a country” (WEF 2011), measuring countries and placing them in the global ranking order. The WEF defines their most recent (2020) GCI Report as “the Global Competitiveness Report has since its first edition aimed to prompt policy makers beyond short-term growth and to aim for long-run prosperity. The 2020 special edition is dedicated to elaborating on the priorities for recovery and revival, and considering the building blocks of a transformation toward new economic systems that combine ‘productivity’, ‘people’ and ‘planet’ targets” (WEF 2020).

Neither at the national level, “despite its importance, a fully operational model to be used in any context has not yet been designed” (Popescu et al. 2017). However, the authors evaluate and analyze

sustainable competitiveness from the macroeconomic perspective via three factors: the economic, the social, and the natural, and utilization of four indexes (Human Development Index, Environmental Performance Index, Global Competitiveness Index, and GDP per capita) (Popescu et al. 2017). However, they conclude that “these indices are not able to offer exhaustive image of the sustainable performances assessment” (Popescu et al. 2017, p. 24). “Is it possible for a country to be commercially competitive and at the same time protect the environment and social welfare?” has been asked and explored (Thore and Tarverdyan 2016).

At a firm level, as an example of measurement elements, one model suggests including the factors of innovation and training; social capital; resource efficiency and environmental compatibility; stakeholder relationship management; and management capital (Salimova et al. 2018, p. 167).

How To Implement Sustainable Competitiveness?

While the definition of the term sustainable competitiveness and the underpinning terms of are not yet agreed upon, the problem of implementation calls for solution, offering paths for future studies (Adams et al. 2016). Business models play a role in relation to sustainability innovation (Rohrbeck et al. 2013). The search for a sustainability related business model at the same questions the current neo-liberalistic lens on the world (Adams et al. 2016; Boons and Lüdeke-Freund 2013).

However, as the question of implementation is of significance and its meaning is likely to increase in the future (Adams et al. 2016), ways to apply and implement sustainable competitiveness have been and can be suggested from various perspectives.

At an organization level, a possibility to implement sustainable competitiveness comes via implementation of international standards. The International Organization for Standardization (ISO) is one of the organizations providing global

standards. Approached from the perspective of sustainable development of society (ISO 2017), Salimova et al. have proposed to utilize five ISO standards: ISO 9001:2015 Quality Management systems; ISO 9004:2018 Quality Management – Quality of an organization – Guidance to achieve sustained success; ISO 14001:2015 Environmental Management Systems – Requirements with Guidance for use; ISO 26000:2010 Guidance on social responsibility; and ISO 22301:2012 Societal Security – Business Continuity management systems – Requirements (Salimova et al. 2018). Further, it has been suggested if and how the ISO 31000:2018 Risk management standard and the ISO 31022:2020 Guidelines for the management of legal risk could help to advance sustainability and address sustainability-related risks and mitigate them (Hirvonen-Ere 2019). In addition, at a country (regional) level, proper risk management has been suggested as a major success factor for a country in its sustainability development (Rutkauskas 2008).

At a corporate level, paraphrasing two old truths of the project management approach (you get what you measure and you get what you reward) a practical implementation guide “What Gets Measured Gets Done” has been created to implement what is termed “Dynamic Corporate Sustainability” (Solability 2022c).

Further, at a firm level, utilization of existing means in an expanded and novel manner could be one of those ways. An example of this approach is implementing not only economic competitiveness but also sustainability and the green economy via the contract management mode of operation to cover the company’s business contracts and contracting activity to promote the headway of sustainability in the corporate world (Hirvonen-Ere 2019). Business contracts are strategic assets creating competitive advantage, whereas lack of sufficient contract management causes conflicts, losses, and value erosion (Cummins 2015). “In addition to business goals measured by direct monetary value, Contract Management can be used in an expanded manner...to drive other types of business goals, such as breakthrough of sustainability” (Hirvonen-Ere 2022, p. 293).

Summary

During the past three decades since the 1980s, the concept of sustainable competitiveness has developed and lived from the plain economic approach to include social and environmental dimensions. Sustainable competitiveness is often approached from the firm level, regional level, national level or international (global) level, or a combination of those, moving from the microeconomic view toward the macroeconomic perspective. At the company level, the concept has transformed from the solely economic concept of the company to produce a gap and win its rival companies, and be able to sustain this competitive advantage, to include the environmental and social aspects as sources of bringing the organization strategic competitive advantage. At the national level and in the international and global comparisons, the gross domestic product (GDP) is no longer considered as a sufficient indicator to measure sustainable competitiveness; it has expanded to combine the plain economic aspect with the environmental and social dimensions and a balance between them.

A commonly cited index to measure competitiveness is the global competitiveness index (GCI) by the World Economic Forum, which has defined competitiveness as “the set of institutions, policies and factors that determine the level of productivity of a country” (WEF 2011) and sustainable competitiveness as “the set of institutions, policies, and factors which make a nation productive over the long term while ensuring social and environmental sustainability” (WEF 2015). A cited index to measure sustainable competitiveness is the global sustainable competitiveness index (GSCI) by Solability, that has defined the term as follows: “Sustainable competitiveness is the ability to generate and sustain inclusive wealth without diminishing the future capability of sustaining or increasing current wealth levels.” Both definitions include the economic, social, and environmental dimension.

However, despite a massive amount of research and reports on sustainability and competitiveness, and a growing number of studies on

sustainable competitiveness, there is no unanimous agreement on the definition, concept, model, measurement nor the interpretation of the outcomes of such measurements. Even though many agree that prosperity and economic growth promote social and environmental sustainability, the growth ideal and current neo-liberalistic world scheme have also been questioned in the search of a sustainability-related business model.

For the aforesaid reasons and because the significance of the topic is expected to continue to grow also hereafter, the theme provides broad avenues for future research.

Sustainable Construction Management

Green construction

Definition

Construction activities change the world into a more suitable habitat for humans and make up the built environment. Hence, construction consumes resources, processes them into desired products and end products, utilizes them, and disposes of them at the end of their life. Therefore, the construction industry lies at the core of human-induced unsustainable ways of living. Meanwhile, sustainable construction management tries to assess the environmental, social, and economic impacts of construction works to reach a more sustainable way of living. While the first sustainable practices tended to focus on energy and resource consumption, nowadays quantitative approaches that look at the whole life cycle can be used in evaluating environmental impacts. In this context, environmental aspects can be determined according to the use of resources, waste generation, disposal, and environmental impacts. Social aspects deal with sustainable living and include safety and security, health and comfort, accessibility, adaptability to climate change, and maintenance. While the construction industry generates many jobs and income, the economic aspects of a project usually examine life cycle costs wholly or in part. Since many of the aspects are interrelated, and their assessment and management rely on evaluation criteria. The adoption of sustainable construction practices not enforced by law is a participatory process involving many stakeholders in the industry. The barriers and necessary actions for adoption are mainly related to the

awareness, knowledge, and understanding of the practice.

Key Issues

There has been significant progress since the inception of the aim to achieve sustainability in construction works. At first, sustainability was more concerned with issues of energy and resource efficiency as evidenced by Kibert's (1994) definition of sustainable construction as "the creation and operation of a healthy built environment based on ecological principles and resource efficiency." Later, a more holistic point of view that also regards socio-economic issues developed. For emphasis, Kibert's definition evolved to "how the construction industry together with its product the 'built environment'... can contribute to the sustainability of the earth including its human and non-human inhabitants" (Kibert 2007). While the sustainable construction concept has the pillars of sustainability (environment, society, and economy) at its core, the triple bottom line approach to sustainability, which recommends that management should focus on 3P's (people, planet, and pocketbook), also holds true.

Successful implementations have shown that a sustainable way of doing things works better than conventional constructional practices in many areas; some of the best practices are established as legislative requirements. Therefore, a shift to a new model of sustainable construction practices from business as usual is necessary. According to Agenda 21, this shift would be easier in developing countries (du Plessis 2002). Yet, the management process is participatory and requires input from many stakeholders. Nonetheless, the situation in each locality, industry, and society differs according to drivers and barriers. The most common barriers include a lack of client understanding, knowledge, and processes in the construction sector. At the same time, the most significant drivers besides improving the quality of life are environmental sustainability indicators. Therefore, the most effective actions to promote sustainable practices are related to the awareness, knowledge, and understanding of sustainable

construction, in addition to the development of new concepts and services (Durdyev et al. 2018; Häkkinen and Belloni 2011). Yet, approaching specific situations instead of general barriers is the key to successful adoption. Also, a way to enable all the stakeholders to work together is necessary. On this basis, tools such as a sustainability performance checklist (Shen et al. 2007), a corporate indicator system (Zhao et al. 2012), and an alliance contract model (Kivilä et al. 2017) are developed.

Assessment Criteria

Various terms identify sustainability in the construction sector. For example, green building systems aim to decrease environmental loads and are evolving in a more sustainability-oriented direction, yet they are still more involved with the construction phase. In contrast, zero energy, negative energy, nearly zero energy, or zero emission building schemes mainly consider the use phase. However, a whole life cycle approach is necessary for holistic sustainable construction management; meaning product, construction process, use and maintenance, end of life and benefits, and loads beyond the life cycle system boundaries must be identified for sustainable construction management. Such a lifecycle-based approach as a decision support tool is defined in the European schemes, specifically CEN/TC 350 "Sustainability of construction works." Fig. 1 shows the notable criteria that require assessment and management concerning the pillars of sustainability. Accordingly, environmental aspects related to the use of resources, waste generation and disposal, and environmental impacts can be determined. Socio-economic aspects include safety and security, health and comfort, accessibility, adaptability to climate change, maintenance, and life cycle costs. Meanwhile, many of the aspects are interrelated, and their assessment is discussed below.

Environmental Criteria

Global environmental problems continue to increase along with the increase in human population and needs. Many studies examined and

Sustainable Construction Management,

Fig. 1 Criteria to be assessed and managed concerning the aspects of sustainability

determined criteria for the environmental aspect of construction practices, since around 40% of carbon and other greenhouse gas emissions, in addition to 40% of worldwide energy consumption, is related to the construction industry. Also, this industry consumes almost 50% of global raw materials and 16% of water (Pacheco-Torgal 2015). Moreover, the waste generated from construction and demolition activities accounts for around half of the global solid waste. The amount of solid waste due to construction sector is 1.2 billion tons in 2012, and it is expected to increase to 2.2 billion tons in 2025 (Transparency Market Research 2018). Therefore, most of the studies on the built environment emphasize the necessity to focus on constructions that manage energy and material resources more efficiently and utilize renewable energy resources. Typical approaches to assess and manage the sustainability of a product require methodologies such as life cycle analysis and standard series such as ISO 14000. The lifecycle of the products used for construction show the way for the environmental performance assessment of a building. Here, ISO environmental product declaration (EPD) can be used to distinguish between similar systems and is mandatory for building materials in various countries including European countries.

Socioeconomic Criteria

Social aspects cover subjective phenomena, such as safety and security, accessibility, and

maintenance, and they require both qualitative and quantitative criteria and metrics. Usually, only the use stage of the lifecycle is considered during the social assessment, in other words, stages before and after use are excluded from the analysis. While most of the social criteria are personalized and hard to assess, building codes provide quantitative benchmarks for health and comfort, yet much research still focuses on the determination of more acceptable ranges according to feedback from users. Health and comfort encompass many issues since the frequency of health problems is usually related to indoor environmental quality. Thus, healthy environments cannot be separated from thermal, visual, and acoustic comfort, which are related to indoor air quality, thermophysical properties of the building, spatial characteristics, detailing, building design, specialized products and equipment. In this context, the building envelope and building materials are the common focus of research, since they are directly related to thermal comfort, indoor air quality, and the building's energy consumption.

Sustainable construction is a big industry that is competitive, it generates many green jobs and income. Economic criteria in a construction project is assessed via lifecycle costs in full or partial considerations. In addition, cost plays a significant role in the realization of a project; feasibility studies are important in producing sustainable constructions. Although cost is not considered as

one of the biggest barriers in implementing sustainable constructions, a negative image of sustainable constructions is having high initial costs. However, this may not always be true because the maturity of the market and penetration of sustainable technologies and practices affect costs. Especially in renovations or large-scale constructions, it is possible to decrease building energy requirements and improve various social criteria without increasing the initial investment costs. Many of the criteria are interrelated, and all of them affect the sustainability of development and impacts on the neighborhood.

Summary

The assessment of sustainability criteria leads the way in the management of a project's sustainability. There are multiple criteria regarding the environmental impacts, the use of resources and waste. Feasibility and life cycle analysis can expose the positive and negative effects of alternatives. They are easier to quantify even though their relationship to other sustainability criteria is not a deeply explored research area. Even though criteria for health and comfort have some generally accepted quantitative values in the building codes, most of the social aspects are subjective. For this reason, they are not easy to quantify and require qualitative research and evaluation methods. The research done on environmental issues is remarkably more than socioeconomic pillars of sustainability. However, the sociological dimension of a project is essential to its inception and continuity, since increasing and sharing the knowledge for sustainable constructions help to decrease its undesirable effects.

Careful analysis, management, and spread of best practices in the construction industry result in a decrease of the impacts of new construction projects on the built and natural environment. While the spread of these practices does not show the aspired effects of neutralizing the effects of human-induced loads in a short time frame, the acceptance and adoption of sustainability practices are high. However, there are barriers to the adoption of sustainable construction practices,

including a lack of client understanding, and knowledge and processes, in the construction sector. Therefore, the most beneficial mechanisms to promote such practices are related to education, the sharing of sustainable construction and management protocols, and the development of new concepts. Since sustainable construction management is a holistic and interconnected topic that requires effort from many stakeholders through various points of the construction lifecycle, relationship and communication between the stakeholders are crucial in ensuring the spread of sustainable construction as well as its management.

Introduction

The topic of sustainable consumption is enjoying increasing international attention (Jackson 2007, p. 254) in academic studies and general society (Zaccai 2007). This is due to the fact that well-known environmental as well as social challenges are reaching new tipping points (UNEP 1999, p. 2). Already three of nine planetary boundaries (for more information see the Stockholm Resilience Centre) have been crossed (nitrogen cycle, biodiversity loss, and climate crisis); crossing more could have enormous negative impacts on all of humanity (Rockström et al. 2009). These effects of human impacts can no longer be easily reversed and, as a consequence, affect life on earth (Mont 2019, p. 1).

Today's task is therefore to respect biophysical limits of this planet by reducing global consumption rates (UNEP 2021a), because unsustainable consumption and production patterns make a major negative contribution to current sustainability challenges (UNCED 1992). In 1999, the Global Environmental Outlook 2000 by the United Nations Environmental Programme already emphasized the necessity to reverse the trends of population growth, permanent economic growth, and high consumption patterns or to accept that the environment will suffer significant irreparable damage (UNEP 1999, p. 3). If consumption patterns will not change and with an expected population growth to just under 10 billion by 2050, a total of three planets will be needed to continue the current standard of living (UN 2021a). Even though environmental gains have already been achieved (UNEP 1999, p. 3) through technological solutions such as higher energy efficiencies and climate change mitigations measures, the processes cannot be stopped due to the rapid economic growth, the actual consumption patterns (ipcc 2018), a growing population and the destruction of non-renewable resources (UNEP 1999, p. 3). Therefore, it is of great importance to learn to accept the natural limits of the planet and to reflect this accordingly in consumption and production behavior (UN 2021a), because the way many societies- in particular in the industrialized world- live, use electricity, water, eat, cook, dress, and travel are mayor forces facilitating those challenges (Maxwell 2013, p. 691).

Especially food, transport, and leisure play an overriding role when considering consumption of consumer goods, as they account for a large share of energy demand and energy intensity (Schoot and Anton 2007, p. 37). The reasons for their over-consumption are complex as they are a consequence of the modern consumer society (defra 2003, p. 5). The goals consumers pursue by consumption are very diverse and range from nutrition to pleasure from self-realization to socialization.

However, collective and non-material goods and services, such as security and education, also play a role as societies want products and services

that contribute to an improvement of the quality of life. At the same time, those consumers have difficulties to accept that this also creates negative impacts, thereby making the achievement of a long-term balance between “economic development, environmental protection and social cohesion” impossible (defra 2003, p. 5).

As a consequence the modern consumer society, which consumes (and wastes) more resources than ever before (UNEP 2021c), first needs to understand that rising consumption is having a devastating impact on the entire planet (Maxwell 2013, p. 691). Ecological damage such as depletion of renewable resources, loss of biodiversity (UNEP 2001, p. 17) and forests, extinction of species and generation of hazardous waste are just some of the consequences (UNEP 1999). In addition to ecological damage, there is also social damage, such as poverty, cultural harm and social injustice also resulting in economic damage (UNEP 2001, pp. 17–18).

It is for example estimated that about one third of the food produced ends up in the garbage can (UN 2021a). Consuming those resources in such an unsustainable way also contributes to the gap between rich and poor (UNEP 2021c), because consumption opportunities are very unfairly distributed. While today millions of people have few consumption possibilities and cannot even satisfy their basic needs (UNDP 1998a, p. 41), the others live far beyond their natural limits (UNEP 1999, p. 2). That is because the richest 1% of the population is richer than the entire rest of the planet (Credit Suisse 2016). So while the majority of society is unable to meet food, health care and educational needs, the minority of society is responsible for the environmental degradation (UNCED 1992; UNEP 1999, p. 2).

This social injustice leads to the debate of the human development perspective in relation to sustainable consumption. This perspective considers people independent of their possessions and demands a world in which there is justice in terms of consumption, equal opportunities and potential. It is therefore important to emphasize that poorer social classes should at least be given the opportunity to make their own consumption decisions (UNDP 1998a, pp. 39–41). Hence it is

comprehensible that emerging economies also want to adopt the modern consumer patterns (Dobré 2007, p. 167), even though studies have found that more consumption does not make society happier. After reaching a certain level, the sense of well-being is detached from materialistic goods (Jackson 2009). Also it should be stated here that countries with excessive consumption rates also are more likely to deal with diseases resulting from over-consumption (Nkamnebe 2013, p. 2427).

To summarize, it is important to state here, that while poorer countries are struggling hard to maintain an improved standard of living through consumer choices in the first place, richer countries are already trying to make up for the standard of living they have achieved and make it more sustainable (UNDP 1998a, pp. 39–41). The “model of abundance” (Dobré 2007, p. 167) has therefore developed cracks and cannot be carried on forever on the shoulders of the planet and on the natural resources. The difficult thing about this situation is that poorer countries are often dependent on the export of their resources, but requiring to build an economy that is not dependent on exports. While industrialized countries need to move away from permanent growth (as a symbol for positive development) in the long term and become more resource efficient. This is the task (and the duty) for over-consuming nations (Bauchmüller 2021), because a more sustainable consumption could contribute positively to poverty reduction as well as to a low-emission and green economy (UNEP 2021c).

Definitions

This chapter defines important terms regarding sustainable consumption. It includes the terms sustainability, consumption, and sustainable consumption.

Definition Sustainability

Sustainability is described with a three-pillar model that encompasses the economy (e.g., support local economy), ecology (e.g., conservation), and social issues (e.g., fair wages). The three

pillars are seen as overlapping with each other therefore requiring permanent and balanced coordination (Enquete-Kommission 1998). More precisely, sustainability includes the securing of human existence, the preservation of resources, and the assurance of opportunities for action and development for present and future generations (Pufé 2017). Sustainable consumption is based on such a concept of sustainability.

Definition Consumption

In the economist's, the concept of consumption is defined as the use of goods and services by private or public households (Carroll 2021). But according to Stø et al. (2008, p. 247), consumption includes not only the consumption phase itself, but also the upstream and downstream stages of the value chain. These include the upstream stages of production, distribution, planning, and purchasing, but also reshaping, co-production, and the downstream stage of disposals (ibid.). Stern et al. (1997, p. 20) go even further and explicitly mention the accompanying resource use in their definition: "Consumption consists of human and human-induced transformations of materials and energy. Consumption is environmentally important to the extent that it makes materials or energy less available for future use" (Stern et al. 1997, p. 20).

By looking at these different definitions, it becomes apparent that different approaches to the topic of consumption exist. This is because the debates about consumption can be traced back to at least the times of classical philosophy (Jackson 2005, p. 9).

Today, the topic is embedded in various fields of research, such as economics, psychology, sociology, anthropology, and the environmental studies, which illuminate the topic from different angles. Thus, while sociology and anthropology are more concerned with consumption-related group identity, the environmental studies focus more on unsustainability in relation to the environment (Reisch and Thøgersen 2015, p. 1; UNDP 1998a, p. 40).

Definition Sustainable Consumption

The International Institute for Sustainable Development (IISD) defines sustainable consumption

as "The use of goods and services that respond to basic needs and bring a better quality of life, while minimizing the use of natural resources, toxic materials and emissions of waste and pollutants over the lifecycle, so as not to jeopardize the needs of future generations" (IISD 2021). This means that sustainable consumption has to be understood as an umbrella term, which addresses different key issues like resource efficiency, renewable energies, waste management, and the resources life cycle analysis (ibid.). Sustainable consumption therefore involves various disciplines, like "Environmental Science; Business, Management and Accounting; Social Sciences; Economics, Econometrics and Finance; Energy; and Engineering" (Mont 2019, pp. 4–5). Accordingly, it is a contested term that can be illuminated from different angles (Boulanger and Zaccai 2007, p. 238). This is because the approaches behind sustainable consumption has yet to be tested (Jackson 2007, p. 256), as the terminology is still relatively new (Jackson 2005, p. 9).

The History of Sustainable Consumption

Even though consumerism has its roots in the Industrial Revolution, it really took hold in the period after World War II (Lintott 2007, pp. 43–44). The first critiques were already made, among others, by the writer and philosopher Henry Thoreau (Thoreau 1854 reprinted 1992) and the economist and sociologist Thorstein Veblen (Veblen 1899).

However, the concept of over (unsustainable)-consumption was first raised as an issue in the international policy arena by the newly established United Nations (UN) in 1949, the subjects of conservation and use of resources was taken up again at the United Nations Conference on the Human Environment in Stockholm in 1972 (Jackson 2007, p. 255). The same year, the well-known document concerning the Limits of Growth was published by the Club of Rome. It dealt with the depletion of resources due to increasing prosperity and the relevance of consumption patterns regarding environmental problems (Horst 1975). This development

subsequently culminated in the establishment of the United Nations Brundtland Commission in 1983 (Nkamnebe 2013, pp. 2428–2429). The commission addressed “the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development” (UN 1987).

As a result, the topic of sustainable consumption has been an integral part of international debates since the early 1990s (Mont 2019, p. 4) and culminated in the Earth Summit in Rio de Janeiro in 1992 (Nkamnebe 2013, pp. 2428–2429). At this United Nations Conference on Environment and Development (UNCED), it was officially recognized that current consumption patterns are not sustainable (UNEP 2001, p. 11). The developed Agenda 21 therefore explicitly dealt with changing consumption patterns in Chap. 4. The following action plan focused first on unsustainable production and consumption behaviors before moving on to national policy strategies to bring out a change towards sustainable consumption (UNCED 1992). Therefore the popularization of the term sustainable consumption can be dated back to Agenda 21 (Jackson 2007, p. 255) meaning that this field of research is about 30 years old (Mont 2019, p. 4).

In the years that followed, much changed in the area of sustainable consumption. These included, for example, the roundtable held in Oslo in the year of 1994, which was attended by companies, NGO’s, and government representatives (IISD 2021). In 1995, the UN launched another program, the International Work Programme on Changing Consumption and Production Patterns (IWPCPP), which focuses on changing consumption patterns (UNEP 2001, p. 11).

This program also led to an Earth Summit II in 1997, which is also known as the Rio + 5 conference (Jackson 2007, pp. 255–256). In the process, the issue of sustainable consumption was recognized as a cross-cutting issue of sustainable development (UNEP 2001, p. 11). The 1998 published Human Development Report also focused explicitly on this issue. It showed that, from a global perspective, consumption is very unequally

distributed, leading to major inequalities (UNDP 1998b). The Commission on Sustainable Development (CSD), therefore met in New York in 1999 on this topic and developed guidelines for developed and developing countries (CSD 1999). During the World Summit on Sustainable Development (WSSD) in Johannesburg in the year of 2002, the participants also discussed the implementation of Agenda 21 and the continuation of further goals in the field of sustainable consumption until 2015 (UN 2002; Zaccāi 2007, p. 1).

According to the brief summary of the historical development of sustainable consumption, the roots of the current understanding were established in the late 1990s. Since then many initiatives evolved (Jackson 2007, pp. 255–256). This includes, above all, the work of the CSD, the United Nations Environmental Programme (UNEP) and the Organization for Economic Cooperation and Development (OECD) (Fuchs and Lorek 2005, p. 263). Within the work of UNEP, special mention should be made of the Sustainable Consumption Network, which in 2001 published a document dealing with the integration of sustainable consumption policies into consumer protection guidelines. The focus was particularly on the possibilities and opportunities offered by the new sustainable consumption focus (UNEP 2001). The UK government was one of the first to recognize those necessities and opportunities and published a national strategy on sustainable consumption in 2003. The framework was developed by the Department for Environmental, Food and Rural Affairs (DEFRA) together with The Department of Trade and Industry (DTI), which developed twelve strategy points (defra 2003; DTI 2003; HM Government 2005). Among the strategy points identified were the decoupling of economic growth and environmental degradation (which will be discussed later), consideration of the entire life cycle, and explicit policy design measures to achieve the targets (DTI 2003).

Another major milestone was the WSSD a few years later, in 2002. There the international global commitment to make consumption sustainable in the future was solidified in the 10-Year Framework of programs on sustainable consumption

and production also reflected in Goal 12 of the Sustainable Development Goals (SDG's) (UNEP 2021b). The SDG's are the result of decades of discussion by the UN, including United Nations Department of Economic and Social Affairs (UNDESA), and were signed by all member states in 2015. They are based on the 17 Millennium Development Goals (MDG's) developed in 2000, (UN 2021b).

SDG Goal 12 (Responsible Consumption and Production) of the Agenda 2030 is further subdivided into 11 targets and 13 indicators that deal, among other things, with sustainable production and consumption patterns, resource-conserving behavior patterns and the Circular Economy. A monitoring approach of the targets is ensured by means of developed hotspot analysis tools as well as the OnePlanet Initiative for sustainable consumption and production (UNEP 2021a). The overall aim of these initiatives is to ensure that as few natural and toxic resources as possible are consumed throughout the production and consumption process and that as little waste and pollutants as possible are generated. The aim is to fulfill three holistic goals, which are the decoupling the environmental degradation from the economic growth, keeping the life cycle in mind and shaping fair opportunities for developing countries regarding efficient resource management and the creation of green jobs (UNEP 2021c).

As the historical overview indicates, many sustainable consumption policies and strategies have been developed over the years but many countries are still struggling with their implementation. In summary, it is regrettable that the implementation and translation of these policies and strategies at both the national and international levels has been lacking (Jackson 2007). As a result, no fundamental changes in consumer behavior have been identified at this point. On the contrary, it has been found that the increasing consumption of green products has rather led to a rebound effect (Schultz and Stieß 2008, p. 289). Accordingly, it must be said that there is an assumption that companies only consider sustainable production and consumption if their profit is not affected. Also, national governments act in such a way

that the issue is ignored if the general income level cannot support sustainable consumption (Nkamnebe 2013, p. 2434). This leads to argue that the implementation of sustainable consumption faces many challenges.

Challenges for Sustainable Consumption

Consumption decisions can no longer be explained with the classical economic approach, but only with more dynamic and complex models including sociology, psychology, and situational variables (Rousseau and Bontinckx 2007, p. 73). Additionally, consumption is dependent on a variety of factors: personality and motivation, the social situation of the consumer, the place of living, the age and the society the consumer is surrounded by (Wallenborn 2007, p. 68). Thereby, consumption is understood as a way of expressing communication with others in a social context through social conversations about "status, identity, social cohesion, and the pursuit of personal and cultural meaning" (Jackson 2007, p. 261). Therefore the consumption behavior results from social expectations and thus from social norms as well as from pure habits (Spaargaren and van Vliet 2000). This makes the development of policy in the direction of consumer behavior change very difficult to bring about (Jackson 2005, p. 3). Cialdini et al. (1991, pp. 203–230), for example, state that the individual behavior is the copy of the behavior of others around. In doing so, people usually always follow two norms. The descriptive norm of "is," which characterizes what most people do, and the injunctive norm of "should". This denotes the perception of what most people perceive as right or wrong. Since it is argued that norms strongly influence human behavior, they also have a strong impact on consumer patterns (ibid.). Accordingly, the roots of normal consumer habits do not lie with each individual, but in the behavior of the masses (Jackson 2007, pp. 262–264). Moreover, the phenomenon of social inertia can also be identified. It states that no one will change their consumption habits, as no sustainable consumption behavior is visible in society either (Goldsmith and Bacille 2015,

p. 150). In doing so, humans always strive to adjust their consumption level to the consumption of fellow human beings or even to surpass it.

However, in the long term, the global welfare will not change due to the individual adjustment of consumption (Lintott 2007, p. 48). This means that in particular the Western society is locked into a treadmill that promotes unsustainable consumption patterns (Sanne 2002). And since consumption is facilitated by values, institutions, and by socialization, consumer society expresses who they are through their consumption. It must be clearly emphasized here that companies deliberately direct consumption according to their interests through targeted marketing, and that governments also exert a strong influence on consumption patterns according to the economic paradigm (Lintott 2007, p. 49). It is therefore obvious that incentives and pressure encourage people to consume (Rousseau and Bontinckx 2007, p. 73), which means that institutional barriers are stopping the development to a more sustainable consumption (Goldsmith and Bacille 2015, p. 150).

Additionally, in order to bring about sustainable consumption, it is not merely about the issue of reducing the consumption, but also general structural factors such as changes to “working life conditions, urban structure and everyday life patterns” (Sanne 2002, pp. 273–274).

In addition to consumers, governments as well as industry represent the most important stakeholders in the area of consumption (UNEP 2001, p. 16). However, at the point of decision-making it is the consumer, who holds the power to lead the way toward sustainable consumption (Mont and Power 2013). This argument is supported by the increasing awareness of current consumers regarding which products they consume and how and where these products come from. This leads to stronger pressure on all stakeholders to foster a transition to make consumption more sustainable in the long term (UNEP 2001, p. 10).

In addition to the issues already outlined, the topic of sustainable consumption faces further challenges. These include, for example, overcoming the economic incentive to consume (e.g., low raw material prices, low economic benefits for countries, and low recycling rates) to using

economic incentives to reduce resource use to a very low level (e.g., higher raw material prices linked to fairer wages and higher economic benefits for nations, higher recycling rates). At the moment, it is often cheaper to buy new equipment than to have it repaired (Bauchmüller 2021).

Moreover, governments constant drive for economic growth in developed and developing countries is a critical issue (Kemp 2008, p. 369), despite the fact that it has been proven that the satisfaction of the majority of inhabitants of developed societies are no longer dependent on material goods above a certain level. However, the economic systems of those countries rely on perpetual consumption to retain a growing economy.

This is where sustainable consumption comes into action focusing on the improvement of the quality of life of society and economic wealth, while insuring a lower resource input. This term is referred to as decoupling (UNEP 2001, p. 15). The difficulty behind this approach, however, is the fear of economic growth coming to a standstill, followed by a subsequent recession and high unemployment. Modern governments therefore do not choose or consider this path, even if it is possible to continue to experience economic growth as long as the decoupling of economic spending from material resources is more rapid (Jackson 2007, p. 258).

Decoupling is seen as an important part of achieving sustainable consumption in the long term and a “more socially inclusive global economy” (UNEP 2021a). According to IISD (2021), it is possible to increase revenues while reducing resource consumption without any problems. Nevertheless this will sometimes lead to conflicts between economic growth and sustainable consumption (ibid.), and therefore needs a more sophisticated understanding (Jackson 2007, p. 259).

Future Directions and Solutions for Sustainable Consumption

The challenges described in the previous chapter can quickly lead to a pessimistic assumption on the topic of change toward more sustainable

consumption patterns. Nevertheless, it is important to recognize that the pressure created by the continuous increase of negative environmental change accompanied by growing consumption will lead to a poorer quality of life. Accordingly, it is expected that this development will exert a general pressure on all stakeholders with the consequence to work together (Lintott 2007, p. 53). This is expected not only in Western countries, but worldwide, since humanity ultimately shares one planet with limited resources (Schoot and Anton 2007, p. 39). However, to bring about change, there first has to be a recognition of the issue and secondly, the development of new remedial and redesign measures. These measures should be considered as soon as possible, as unsustainable consumption is responsible for large shares of greenhouse gas emissions and thus has a major effect on climate change (Genus 2016, p. 143). The options that are seen as possible solutions to this problem can be divided into two categories: The reorientation of the production and consumption patterns and the involvement of all stakeholders.

Reorientation of Production and Consumption Patterns

Making production and consumption sustainable in the long term will require major transformations of existing behavior, especially in industrialized societies, but also the abdication of developing societies to achieve a Western lifestyle. This symbolizes another major (unjustified and unfair) ask of developed countries to developing countries.

In general, it requires a promotion of already existing positive trends and a reorientation of the entire production and consumption process (UNCED 1992). At this point in time the focus is on making consumption more efficient and environmentally friendly, but it is more important that the volume of consumption (in particular of nonrenewable resources) decreases in the long term (IISD 2021).

The following approaches are seen as possibilities to reduce waste and pollutants and use as few finite resources and energy as possible in the whole production process (UNCED 1992). This includes the Eco Design Framework as well as the

Life-cycle Approach and the Integrated Product Policy (DTI 2003) to drive a change to produce products and services with a lower environmental impact along the entire supply chain (HM Government 2005, p. 43). It also includes, for example, that non-sustainable products need to be replaced by more sustainable alternatives (IISD 2021).

Another important model is the Circular Economy. It aims to re-use, re-manufacture, recycle and recover materials to preserve them for as long as possible (UNEP 2021a). At the moment, only 12% of the raw materials processed for consumption are returned to the production cycle. Already, improved deposit systems, the application of the Sharing Economy, and product design guidelines are used to address this problem.

Other tools are, for example, the taxation of CO₂ emissions created by production processes and the increase in product prices (Bauchmüller 2021). This can be understood as the internalization of external costs in order to send clear signals to the market to change or optimize their production processes. It goes in conjunction with the elimination of negative tax incentives that motivate unsustainable behavior (Maxwell 2013, pp. 691–692).

However, in the past it was observed that price signals are often not sufficient to induce more sustainable consumption behavior as cost-efficient decisions are not implemented. This is precisely where policymakers need to start and help to make sustainable consumption options available to the customers (Jackson 2007, pp. 262–263). One fundamental option would be to reduce working hours, because “[w]ork and consumption are the two sides of the coin of the economy” (Sanne 2002, pp. 279–285). As the amount of work done also defines the level of consumption, not only individually but also nationally, reduced working hours is proposed to lead to lower consumer spending. However, such changes in lifestyle could undermine overall economic growth (*ibid.*) and therefore threaten the current economic system.

Such a change goes hand in hand with the decoupling approach, which states that economic growth needs **not** be accompanied by

environmental degradation (UNEP 2021c). It is done through the so-called efficiency approach behind decoupling process. It can be understood as an answer to the dilemma of economic growth (Jackson 2009, p. 68). Sustainable production can thus be achieved on the basis of dematerialization, which describes both product efficiency (using less) and process efficiency (doing less). Thus, overall economic growth can still be achieved, but with fewer resources and lower pollutants.

Nevertheless, it must also be added at this point that dematerialization also comes up against natural efficiencies especially when the increasing consumption and the rising population rates are taken into consideration (UNEP 2001, pp. 27–30). This is where the change in consumer behavior comes into play, which can make an important contribution through optimization. Optimization can be divided into three aspects at this point: Different consumption (changing infrastructure and choices), conscious consumption (choosing and using more consciously) and appropriate consumption (questioning levels and drivers of consumption) (UNEP 2001, p. 31). This is also an important component on the way to sustainable consumption and is brought about by growing awareness of social and ecological concerns in society (HM Government 2005, p. 43). In order to achieve such, a multifaceted strategy is needed to cover the topic holistically (UNCED 1992). And this are also necessary, because while there is great potential for improved product and production processes, sustainable consumption can only be brought about if consumers themselves also participate in this process (HM Government 2005, p. 51).

Already, consumers expect to be able to adopt more sustainable consumption patterns in the future, therefore demanding change. This is due to the fact that consumers realize that they are seen as having a great deal of power in terms of sustainable consumption developments (Wallenborn 2007, p. 57). Accordingly, business will have to adopt a consumer perspective including a holistic approach to find solutions to satisfy a demand for more sustainable consumption. It should take into account the “attitudes, routines and the organisation of everyday life” (Schultz and Stieß 2008,

p. 288), regarding society’s consumption patterns (ibid.). By adopting the consumer perspective, the provision of information and communication with consumers can be improved in the long term. This can also lead to an improvement in the “product design, innovation strategies and sustainability policies” (Schultz and Stieß 2008, p. 298). Sustainable consumption possibilities could facilitate better health, a cleaner environment, and greater interactivity in society. Such an improved quality of life at less cost and with positive cultural and personal development options is enhanced through conscious and appropriate consumption (UNEP 2001, pp. 60–61), but it also needs the involvement of all stakeholders.

Involving Stakeholders

It has already become clear from the previous chapters that a number of stakeholders are involved in the area of sustainable consumption. In order to do justice to a holistic approach, it is therefore of great importance to include all stakeholders in the change processes (UNEP 2001, p. 62). Individual actors without sufficient knowledge and power are not enough as the shift toward a more sustainable consumption calls for an enormous paradigm shift in society as well as in the economy (Mont 2019, pp. 2–3). Stakeholders from all sectors from all over the world must therefore pull together (UNEP 2021c), while the first initiatives should be started locally and regionally, since consumption is by nature local in the first place (UNEP 2001, p. 14). However, care should be taken to establish a consensus (at least as much as possible) regarding all parties involved to be independent of the short-term interests of individual participants (Nkamnebe 2013, p. 2434). Companies for example can be supported by the government and international industry best practices to get inspirations, financial help, and appropriate management instruments (UNEP 2001, p. 14). Moreover, consequent cost reductions, an improved competitive position, increased market share, and higher consumer confidence can be seen as additional incentives (UNEP 2001, pp. 60–61).

Nevertheless, the shift toward completely sustainable consumption will take many decades. This

is also due to recent stocks of unsustainable consumer goods in the areas of infrastructure and transportation, as well as households, in the energy and waste management sectors. Accordingly, measures to develop alternative plans that favor sustainable consumption choices must be developed progressively with the participation of all stakeholders (IISD 2021). Respectively, collective decisions and structure-changing decisions are necessary to help individuals to frame their buying decisions on sustainable consumption (Lintott 2007, p. 53).

Yet, this should not explicitly disregard the fact that consumers, governments and companies already have opportunities to help shaping consumption in a more sustainable way (IISD 2021). Overall, there is great responsibility on the consumer and voter. Accordingly, experts argue that the focus of the political instruments in the future should be much more on the actual consumption phase in order to ensure sustainable behavior (Stø et al. 2008, p. 251). In this respect, governments linked to governance play a crucial role in identifying new pathways (Mont 2019, pp. 2–3) and provide important leadership and support to individuals and households (UNCED 1992). By political intervention such as implementing international integrated legal policy frameworks, long-term costs resulting from environmental damage can be reduced or eliminated, but competitiveness and the quality of life being improved (UNEP 2001, pp. 60–61). These basic requisites include regulatory intervention through legislation compelling certain consumption patterns, economic intervention through adjustments to the market, and social intervention through awareness-raising or education (UNEP 2001, p. 44). It also contains the increase of information dissemination (Jackson 2007, p. 262). Policymakers are therefore responsible for providing a market that enables society to make efficient and long-term sustainable consumption choices (Jackson 2007, p. 262) moving away from exclusively economic indicators such as gross domestic product and to include natural and social capital in the calculation (Maxwell 2013, pp. 691–692).

Another important stakeholder at the micro or macro level is the industry. Here, the progress is rather gradual and not radical, because sustainable

business activities are constantly revised depending on consumption patterns (Charter et al. 2008, p. 65). Besides consumers and governments, companies and marketers are key players in the creation of new sustainable business models that apply push and pull strategies to foster sustainable innovations. Additionally, non-governmental and the financial organizations are important stakeholders in developing an appropriate framework (Charter et al. 2008, p. 66). In general, there must be a change in perspective when it comes to sustainable business models and corresponding sustainable growth, because these issues are closely linked to the shift toward sustainable consumption (Charter et al. 2008, p. 66).

In summary, it is obvious that sustainable consumption behavior can only be achieved through legal and regulatory means, incentives, far-reaching strategies, and social influence (Goldsmith and Bacille 2015, p. 127). There is a need to develop strategies for sustainable production on the supply side, as well as to create sustainable consumption patterns on the consumer side. Consequently, the focus of policymakers is increasingly shifting to the interest groups that have a major influence on consumer choice. These include retailers, brand manufacturers, educators, and the media (Maxwell 2013, pp. 691–692). Only in this way can long-term strategies change consumption patterns, bring about resource efficiency, implement economic transformation, and thus maintain the standard of living of the rich while improving the standard of living of the poor. On a broad scale, sustainability can be achieved and environmental degradation prevented (UNEP 1999, p. 16). But even though the consequences for consumers, producers, and politicians are clear, it can be assumed that it will take decades rather than years to bring about a general change. Accordingly, it will take commitment, compassion, and patience from all stakeholders involved (Schoot and Anton 2007, p. 39).

Summary

The research field of sustainable consumption is already about 30 years old and includes multi-

disciplinary fields. Especially in the 1990s, major developments were noted as local, national, as well as international attempts were made to implement sustainable consumption patterns.

Overall, the complexity of the topic is evident and the necessity of acting has been clearly identified. Current consumption patterns in particular in developed countries or society in combination with global population growth, environmental limits of the planet are exceeded. The Western consumption patterns also lead to a growing imbalance between rich and poor. A shift toward sustainable consumption can reduce these negative impacts overall and lead to poverty reduction, lower emissions, and a greener economy.

Though, it must be noted that despite sustainable consumption policies and strategies, the implementation of sustainable consumption proves to be difficult. It is also reflected in the consumption behavior, which has hardly changed so far. This is also due to the nature of consumption as it is strongly influenced by social norms and embeds humans in social structures. Accordingly, the roots of consumption do not only lie in each individual, but also in the social behavior of the masses. Consequently, there is a need for a general adjustment of lifestyles, working methods, and general behavior patterns combined with a change in values, attitudes, knowledge, and symbolic aspects of consumption, habits, and routines. Correspondingly, the change toward sustainable consumption will take some time, because societies are still locked in a market that promotes sustainable consumption patterns and linked changes only to a limited extent. Even so, a development toward more conscious consumption and production on the part of consumers and producers can already be observed. Currently, production efficiencies achieved are quickly cancelled out by the rising consumption trend and population growth. Hence, there is no way around reducing the volume of consumption in the long term, which means that adopting the consumer perspective is one approach to bringing about general changes in behavior. In this respect, the approach of decoupling economic growth is also an important component on the way to sustainable

consumption. This requires the involvement of all stakeholders in order to implement a holistic approach. Only with an enormous paradigm shift in society, politics, and the economy can the goal of sustainable consumption be achieved. This requires collaboration across disciplinary boundaries, remodeling of economic and social processes, and long-term strategies and considerations. Only sophisticated approaches can thus lead to a long-term improvement in the quality of life, use of resources more efficiently, bring about behavioral changes, contribute to a reduction in poverty, and reduce environmental degradation.

Sustainable Corporate Responsibility (SCR)

Mathias Schüz

Professor emeritus for Responsible Leadership, department of International Business, Zurich University of Applied Sciences (ZHAW), Winterthur, Switzerland

Related Terms

Corporate Responsibility (CR), Corporate Social Responsibility (CSR), Socially Responsible Corporation (SRC), Strategic Corporate Social Responsibility (SCSR), Ethical Responsibility, Corporate Citizenship, Triple Bottom Line (TBL), ESG (Environmental, Social, Governance), Corporate Governance, Creating Shared

Value (CSV), Responsible Leadership, Business Ethics.

Definition

Companies and their management meet sustainable responsibility when they reasonably justify the consequences of their actions towards all affected stakeholders and natural environment, be they present or in the future.

To the Term

Sustainable corporate responsibility (SCR) specifies the concept of corporate (social) responsibility (CSR). This is to be perceived as sustainable, that is, long-term, not only with regard to present generations, but also with regard to future generations. The fact that an enterprise company, that is, a “producing economic unit” (Enderle 1993, p. 1094), is ascribed any responsibility at all is the result of a longer evolution of the concept of responsibility.

The word *responsible* has its origin in Roman law and is a translation of the Latin *respondere* in the sense of *answering an accusation*, which has its roots in the Greek word *spendein*. This, in turn, refers to the giving of a libation at the conclusion of a contract in which something is agreed and assured. The conclusion of a contract was a sacred act, sealed before a divine authority. In the *respondere*, the question of the judge was answered as to whether the obligation had been fulfilled or not (Schüz 2017, p. 11).

In general, *responsibility* represents a “concept of action” (Schüz 2021, p. 22). Unlike behavior, which occurs involuntarily, action is based on a conscious decision with the goal of realizing certain consequences and avoiding others. However, the consequences of an action do not only fulfill the intentions of the causer, but often have unintended effects on uninvolved third parties. As affected parties, they sue the causers for justification of their actions. They should answer for the consequences of their actions to those parties. Depending on the answer

given, the polluter is attributed not only factual but also moral guilt.

In this context, responsibility can be attributed less and less to single individuals, but more and more to social systems – in which, due to the division of labor, a large number of decision-makers can be held responsible for the consequences of their activities. Business enterprises are therefore ascribed corporate responsibility.

Brief History of Corporate Responsibility

The fact that economic activities should not serve self-enrichment but the good of society was already established in antiquity. According to Aristotle, they should be based on “just exchange,” that is, on a balance of give and take (cf. Soudek, 1952, p. 66 f). According to Georg Simmel, exchange is the middle ground “between robbery and charity” (1989, p. 86; see Fig. 1) – in which all parties to the exchange experience an increase in value. When all exchange partners provide fair exchange, it serves the good survival of any community, a point later echoed by Adam Smith (Aristotle 2009, 1132b10–20; Cordero 1988, p. 682; Smith 2016, p. 83; Schüz 2021, pp. 40–48).

According to Nicholas Eberstadt, “business has traditionally been ... a tightly regulated

instrument of social development” (1973, p. 77). With the Industrial Revolution, the centuries-old practice of reciprocity in business and society came to an end.

As a result, however, the concept of responsibility explicitly gained importance in the nineteenth century, as a reaction to the fundamental change that human action underwent in the transition from traditional to modern society (Bayertz 1993, p. 25). This is because industrialization, with its machine-based production and division of labor, made it increasingly difficult to attribute the consequences of action to single individuals: “There is no longer a direct and linear relationship between the actor and the consequence he produces” (ibid. p. 25, translated by author). The damage caused now has a social dimension, if, for example, it contributed to the impoverishment of whole strata of the population or to their health being threatened.

Exemplary for this in the USA is the “Gilded Age” (after the satirical novel of the same name by Mark Twain) in the nineteenth century after the Civil War. During this period, industrialists such as Cornelius Vanderbilt or John D. Rockefeller gained a dominant position in certain markets using questionable, sometimes extortionate methods. Rockefeller at times had a 90% market share with his Standard Oil Company (Cannon 2012, p. 6). “It was a period where greedy, corrupt industrialists, bankers and politicians enjoyed

Sustainable Corporate Responsibility (SCR), Fig. 1 Fair Exchange in the middle of robbery and charity. (Source: adapted from Schüz 2021, p. 49)

extraordinary wealth and opulence at the expense of the working class“ (History.com 2018).

John Maurice Clark may have been the first to call for a new understanding of responsibility in economics as early as 1916 (cf. Shute 1997). The “laissez-faire” or “liberal economics” of the nineteenth century led to an “economics of irresponsibility” by “separating business sharply off from the rest of life” (Clark 1916, p. 218). In turn, the call for a governmental “economics of control” (ibid. p. 221) grew louder.

The Theodore Roosevelt Administration broke up the monopolies of the “robber barons” with “trust busting” – such as the Standard Oil Company into 38 individual companies in 1911 (Cannon 2012, p. 8; cf. History.com 2018). And the industry’s life-threatening technologies had to be controlled via legal safety regulations for the “welfare of the public as a whole.” Steam Boiler laws (first in the United States: 1852), for example, were intended to curb deaths from steam boiler explosions, which numbered in the thousands (Burke 1975, 331f).

Clark suggested that laws can never cover all problems arising from business activities. He therefore argues for a “business responsibility beyond the law ... enforced by mutual interests” of all involved parties (Clark 1916, p. 227). In this context, it is above all necessary to assume responsibility for such courses of action on whose effects the decision-maker has an influence in business life: “Which are the causes over which we have some control and before which we do not stand entirely helpless?” (ibid., p. 214). In his extensive textbook ► *Social Control of Business*, Clark worked out the possibilities of a socially responsible economy already in 1926. Thereby for him “fair” business is “the system of social cooperation by mutual exchange,” which is neither “charity” nor “warfare” (1939, p. 11).

The debate as to whether laws should curb the harmful greed of companies for profit or whether they themselves should assume greater social responsibility was discussed in detail in 1932 in the so-called “Berle-Dodd debate” (cf. Macintosh 1999). Merick Dodd’s idea of a “Socially Responsible Corporation” (SRC) was the antithesis of Adolf Augustus Berle’s demand for legal control

of companies that were only concerned with profit maximization.

The first systematic approach to the “*social responsibilities of the businessman*” was provided in 1953 by Howard R. Bowen in his book of the same name. The businessman should “recognize the social implications of his decisions and to consider the social interest - as far as is possible and reasonable” (Bowen 2013 [1953], p. 30). As Acquier et al. point out, Bowen’s book provides a “systemic concept” that includes “historical, institutional, political, managerial, psychological, moral, and economic” dimensions. “Each is related to the others. Each contributes to or can defeat the purpose of the whole” (2011, p. 625, 629). Clarence C. Walton first summarized the concepts under the title “*Corporate Social Responsibilities*” (CSR), which had been further developed by then, in (1967). More detailed history and evolution of CSR are described – among others – by Archie Carroll and Jill Brown (2018), particularly by Latapi Agudelo et al. (2019), and also by Freeman et al. (2020).

The Structure of Responsibility

According to Georg Picht, the basic structure of any responsibility results as a three-digit relation of acting subject (e.g., a company), which has to answer for the consequences of its activities to the principals or affected parties, the authorities, or instances (1969, p. 319 f), which can be represented graphically as a triangular relation:

In this context, the acting subject (e.g., a corporation) can be held accountable not only for the intended, but also for the unintended consequences concerning third parties. Theoretically, the acting subject must respond for *all* consequences (side effects, repercussions, and long-distance effects of its actions) towards *all those* affected (e.g., stakeholders), which would paralyze any action. Only aspects of the consequences and a certain number of instances can be considered at a time.

In view of the complexity of responsibility, the idea of reducing it to one dimension prevailed in business for a long time to keep enterprises free

from any other restrictions. Accordingly, companies have only one responsibility, namely, to make profits: “the social responsibility of business is to increase its profits,” as Milton Friedman put it in a nutshell in 1970 (Friedman 2007). The idea of shareholder-value as the only responsibility corporate world should take became a trend.

The Dimensions of Corporate Responsibility

Between the two extremes of one-dimensional shareholder value responsibility and universal responsibility, the idea of a three-dimensional responsibility was set (e.g., by Barbier 1987), but has later gained worldwide acceptance with John Elkington’s Triple Bottom Line (TBL) (1997). Generally, a company must be accountable for the economic, social, and ecological consequences of its activities. Thus, it must fulfill its responsibility in three dimensions of responsibility: the economic, social, and ecological consequences. It bears a triple responsibility, which can be illustrated by replicating the triangle of responsibility (Fig. 2) thrice (see Fig. 3).

All consequences of entrepreneurial activity must be justifiable in terms of benefit or harm to self-preservation, co-preservation, and preservation of the whole (or, as it is quite often expressed,

profit/prosperity, people, and planet), and they must also be justified vis-à-vis the relevant authorities, respectively, stakeholders. (Schüz 2017, p. 34).

The *triple responsibility* can be reasoned in terms of systems theory as well as philosophy. Sustainable development can only be seen as “interaction among three systems: the biological (and other resource) system (BS), the economic systems (ES), and the social system (SS)” (Barbier 1987, p. 104; see Fig. 6). Philosophically, businesses do not survive solely by pursuing self-preservation (economic dimension to secure prosperity), but – like all other forms of life – also need to co-preserve the social dimension (to protect all the people they are depending on) as well as to preserve the ecological dimension (to preserve our planet which nurtures all life-forms) (cf. Schüz 1999, pp. 40f, 71–81). In other words: “Business is embedded in society and in a physical world” (Freeman et al. 2020, p. 21; see Fig. 4).

Economic Dimension: Technical or Functional Responsibility

This is where functional responsibility comes into play. It aims to ensure that the company technically functions, that it makes its material resources as efficient and profitable as possible in order to create demand with its products and services so that losses are avoided and profits optimized. The shareholders are the decisive authority here, judging the activities as responsible or irresponsible. All methods and tools of business economics contribute to ensure the income for the purpose of survival (Schüz 2017, p. 34).

Social Dimension: Ethical Responsibility

The social dimension refers to ethical responsibility. Ethics is the art of “getting along well with each other” (Schüz 2019, p. 99). In companies, it aims at good social relations with internal and external stakeholders. A closer look at how this can be achieved by the three main ethical approaches (utilitarian, deontological, and virtue ethics) in business ethics see keyword “Ethical Responsibility” (cf. Schüz 2019, p. 116).

Sustainable Corporate Responsibility (SCR), Fig. 4 Strong sustainability model. (Source: The author following SANZ 2009, p. 8)

Ecological Dimension: Aesthetic Responsibility

The ecological dimension refers to aesthetic responsibility. Aesthetics examines how we perceive the environment sensually. Through our sense organs, we grasp what is useful or harmful to our survival. Most negative environmental influences can be immediately tasted, smelled, touched, or heard. The senses usually point the way to which actions are ecologically useful and which are not. However, our civilization-induced way of life has increasingly alienated us from

nature and dulled our senses to it. We have become accustomed to noise, unhealthy air, polluted soil, or water. In addition, the technical exploitation of nature has limited its self-healing powers (Schüz 2017, p. 35). Aesthetic responsibility teaches people to use all their senses again (including intuition), but also measuring apparatus. It sensitizes them to perceive again the negative effects of their actions on their natural environment. With growing sensitivity, their creativity also increases, which shows them the way to adapt creatively and meaningfully to changed circumstances, for example, with the help of visions, new ideas and strategies. (Ibid, p. 37).

Triple Bottom Line: A Trade-off?

Elkington himself recently criticized that while the TBL is respected by countless companies worldwide, it has ultimately been instrumentalized only as a better “accounting model” for profit generation. (Elkington 2018)

Sustainable Corporate Responsibility (SCR), Fig. 5 Mickey Mouse version of the triple bottom line. (Source: The author following SANZ 2009, p. 8)

Ultimately, most corporate leaders see TBL as a trade-off. With this argument, they justify that social and environmental responsibility does not come too much at the expense of economic responsibility. These forms of green and ethics washing can be illustrated by the so-called Mickey Mouse model (SANZ 2009, p. 8; Fig. 5):

However, as we know, companies are part of society, which in turn is embedded in nature (see Fig. 4). Trade-offs therefore only occur when the resulting profit is not based on fair exchange relationships in society *and* nature (Schüz 2021, p. 86). Thus, Freeman et al. see “avoiding trade-off thinking is the essence of the art of management in the new story of business,” for which they can also provide numerous case studies (2020, p. 81).

Sustainable Corporate Responsibility (SCR)

In addition to the concept of corporate responsibility, the concept of *sustainability*, which originated in forestry already at the beginning of the eighteenth century (Grober 2010, p. 115 ff), has become established with the famous definition of the Brundtland Commission. Among many other definitions, it is the most binding: “Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland Commission 1987; cf. Barbier 1987). Ultimately, it states that the economic, social, and ecological dimensions of

Sustainable Corporate Responsibility (SCR), Fig. 6 Only at the intersection (SB) of the three systems does sustainable development take place. (Source: The author according to Barbier 1987, p. 104)

Sustainable Corporate Responsibility (SCR), Fig. 7 Three-pillar model of sustainability. (Source: thwink.org)

responsibility should also be exercised in the *long term for the* benefit of future generations. Thus, in addition to the three spatial dimensions, it introduces the dimension of time. Accordingly, companies should answer four questions before making any decision: “1. Is my behavior useful from an economic point of view? 2. Is my behavior socially acceptable? 3. Is my behavior ecologically sensitive? 4. Will my behavior be tolerable for future generations? “ (Schüz 2019, p. 73).

But how is the time dimension connected with the three space-dimensions? Quite often it is illustrated like a Venn-diagram (Fig. 6) or a roof on the three pillars of responsibility (Fig. 7). If any one of

Sustainable Corporate Responsibility (SCR), Fig. 8 Different scopes of responsibility. (Source: Schüz 2017, p. 37; cf. 2012, p. 11)

Sustainable Corporate Responsibility (SCR), Fig. 9 SCR-Model. (Source: following Schüz 2017, p. 38; 2012, p. 14)

them is weak, then the system as a whole can be seen as unsustainable.

All these models that portray the relationship between the three dimensions of corporate responsibility and sustainability have the disadvantage that they are rigid and do not allow for dynamics. Furthermore, they do not map the individual strengths and weaknesses of organizations or managers in a sustainable responsibility profile. Therefore, Mathias Schüz has developed an own model of sustainable corporate responsibility that compensates such weaknesses (2012) and will be presented in the following section.

A Holistic Model of Sustainable Corporate Responsibility (Winterthur SCR-Model)

Sustainable corporate responsibility can, therefore, be seen as the overall responsibility of a company for all the actions and omissions of its employees. This, however, would be more than the sum of its individual responsibilities, encompassing the interdependent consequences

for current and future generations, as well as the power of the responsible subject.

Few companies would be prepared to recognize, or even accept, such a universal scope of responsibility. For many, their responsibility only goes as far as the avoidance of immediate risks to their own survival (egoistical point of view). Others are concerned with the effect of their actions on immediate exchange partners or stakeholders (reciprocal view). There are some, however, that consider the world as a total, for example, by taking account of the consequences of their actions for whatever exists.

It has been shown that all entrepreneurial activity should be justified economically, socially, and ecologically. As we have also seen, the scope of responsibility varies depending on the level of moral development. According to Lawrence Kohlberg, we can roughly differentiate the pre-conventional, conventional, and postconventional level (Kohlberg 1971, p. 164): It can be restricted to selfish interests, it can involve reciprocal interests, and it can even be altruistic, or even universal. The latter includes the interests of all concerned life forms (Schüz 2019, p. 69 f). In

Example 1: A purely economic family business that considers social and ecological responsibility as well as future generations only if it serves the family's own interests.

Example 2: A fundamentalist environmental organization that relies on volunteers to fund its actions and attracts sponsors through publicity.

Example 3: A pragmatic and idealistic pharmaceutical manufacturer dedicated primarily to the preservation and improvement of human life while preserving natural resources and making profits along the way.

Sustainable Corporate Responsibility (SCR), Fig. 10 Examples of SCR-Profiles. (Source: following Schüz 2021, p. 31)

our triple responsibility model, the different scopes are represented by the height of the responsibility triangles (see Fig. 8).

Now that we have sketched out the spatial dimensions of corporate responsibility, our model should also include the sustainability dimension. Here, too, different degrees of sustainability, from short- to long-term, can be defined. It was, therefore, decided to present the model of corporate responsibility as a clock with three hands whose length represents the respective scope of responsibility within the spatial dimension. The clock hands themselves represent the triangles of responsibility, consisting of subject S, consequences C, and authorities A. The degree of sustainability can be shown by moving a hand clockwise. The model of sustainable corporate responsibility can now be represented as follows (Fig. 9):

Within the economic dimension, for example, the selfish entrepreneur may well be sustainably oriented if he thinks exclusively of inheriting a healthy company for his great-grandchildren, without regard for other future generations. Further possible combinations cannot be discussed in detail here, profiles in Schüz (2017, p. 47). It is left to the reader to flesh out the respective dimensions with his or her own considerations.

Use of the Sustainable Corporate Responsibility Model

The Winterthur SCR-model now allows typical corporate responsibility profiles (see Fig. 10) to be displayed and compared. Briefly, one can see whether a company, as in Fig. 9, for example, is more economically and socially than ecologically oriented and to what extent sustainability is practiced. A comparison is particularly useful within an industry to identify the most balanced company (best practice). However, comparability is only given if the yardstick and catalogue of criteria on which the assessment is based are identical. Target-performance comparisons based on self-assessment and external assessment (audits) of a company are also possible.

Marcel Fischer has programmed the model so that individual responsibility profiles can be created at <https://SCR-Schuez.maecefischer.ch/home> (see Fig. 10). There, for example, rating agencies such as RobecoSAM (www.robeco.com) could enter and illustrate their assessment of the sustainable responsibility of companies as a percentage.

Sustainable Corporate Responsibility (SCR), Fig. 11 Input fields of SCR-online-tool. (Source: Marcel Fischer 2017)

Sustainable Corporate Responsibility (SCR), Table 1 SCR-checklist

®SCR checklist Criteria for acceptance/rejection of a strategic option			
<i>universal: range/sustainability > 66.6% altruistic charity</i> <i>reciprocal: scope/sustainability: 33.3- 66.6% fair exchange</i> <i>range/sustainability: 0-33.3% egoistic/ robbery</i>		Scope [in %]	Sustainability [in %]
I. Economic Dimension: Technical/ Functional Responsibility			
I.1	Efficiency: What values/resources are available to realize the option efficiently?		
I.2	Reciprocity: To what extent are the exchange relationships along the option's value chain fair, i.e. in a balance of give and take?		
I.3	Effectiveness: How effectively does the option promote the investors' vision?		
II Social Dimension: Ethical Responsibility			
II.1	Utility ethics (average of II.1.a. + II.1.b.)		
a	<i>Reciprocity test</i> : Does the action generate fair exchange relations along the value chain with all stakeholders?		
b	<i>Stakeholder discourse test</i> : Has there been a (fictitious or real) discourse with key stakeholders about the planned measure and was this discourse fair and transparent?		
II.2	Duty ethics (average of II.2.a. + II.2.b.)		
a.	<i>Daylight test</i> : How much is the option in line with the law or the company's defined values and could it be made public?		
b.	<i>Universalizability/autonomy test (Categorical Imperative)</i> : To what extent can the option be elevated to a universal principle or does it violate the dignity/autonomy of those affected?		
II.3	Virtue ethics (average of II.3a. + II.3b.)		
a.	<i>Golden Mean Test</i> : How much is the option virtuous, i.e. does it meet the mean between two vices and can be considered a good example or even best practice?		
b.	<i>Empathy test</i> : How would I feel as an affected person if the option were realized (role reversal)?		
III. Ecological dimension: Aesthetic Responsibility			
III.1	Self-reflection: How much does the option - without trade-off - serve the self-, co- or Overall maintenance?		
III.2	Cradle-to-Cradle: To what extent are the side effects (e.g. waste) of the option meaningfully reintegrated into the natural cycle?		
III.3	Wholeness reflection: How does the option fit into the larger whole of nature?		

Source: cf. Schüz 2019, p. 291 f

SCR-Checklist

One can use the following SCR-Checklist (Table 1) to evaluate, for example, a strategic option or a whole

enterprise how far it can be seen as sustainably responsible in all SCR-dimensions. Especially the test questions for the social dimensions reflect the concept of ethical responsibility (see there) (Table 1).

Sustainable Corporate Responsibility (SCR), Fig. 12 SCR-profile as a result of inputs in Fig. 11. (Source: Fischer 2017)

The resulting percentages for each dimension can be entered in Marcel Fischer's online tool (Input fields see Fig. 11). Then the corresponding SCR-profile is obtained (Fig. 12).

Summary

The concept of sustainable corporate responsibility (SCR) highlights the various dimensions, scopes, and degrees of sustainably responsible corporate activities. Historically, it has its roots in the

economics of fair exchange. This can only take place if all those involved in creating value are in a reciprocal relationship of give and take. The SCR model illustrates the possible relationships between economic, social, and ecological responsibility, as well as their scope and degrees of sustainability.

Prof. Dr. phil. Mathias Schüz studied Physics, Philosophy and Educational Theory at the Johannes Gutenberg University of Mainz in Germany. It was in his PhD thesis on the philosophical consequences of quantum physics that he first addressed the subject of responsibility and ethics. After finishing his postgraduate degree, he was initially employed by IBM as a trainee and then moved on to become a key account manager at the company. Together with insurance entrepreneur Rolf Gerling, he later co-initiated the Gerling Academy for Risk Research in Zurich, Switzerland, where he was working for 16 years as a member of the management board, as well as taught and conducted research. He has been employed as a lecturer and professor at the School of Management and Law at Zurich University of Applied Sciences (ZHAW) in Winterthur ever since 2006, where he teaches and researches the subject of strategic management, business ethics, and responsible leadership. He has published numerous articles and books, recently the textbook “Applied Business Ethics” (in German also in second, extended and actualized edition 2021).

Definition/Description

Sustainable development is a widely used concept, and it has been described in many different

ways. In the Brundtland Report, it is defined as follows (WCED 1987, p. 46): “[S]ustainable development is a process of change in which the exploitation of resources, the direction of investments, the orientation of technological development, and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspirations.” More recently, it has been given a broader definition which conveys that there are three principal dimensions: an ecological or an environmental dimension, a social, and an economic one. The social dimension is often split into social and cultural dimensions. The goal of the ecological dimension is the conservation of all living things, resources, and life-supporting systems. The social dimension involves people living together with the goals of peace, equality, and human rights. The economic dimension comprises jobs and income – as a goal their appropriate development. In addition to these three dimensions, some researchers speak also about the fourth one, the political dimension (Fien et al. 2009), but some of them argue that it is not a dimension – instead it is an aspect what has to do with politics, policy, and decision-making as a goal of democracy (Wolff et al. 2017).

Introduction

Everybody is committed to sustainable development, but seeking ways of people for sustainable development is various. The concept of sustainable development emerged out of particular historical context (Robinson 2004). The idea and terminology of “sustainable development” goes back to Robert Prescott-Allen, World Conservation Union (IUCN) staff writer and principal author of the 1980 World Conservation Strategy. In the Section 13.1, it has been stated (IUCN 1980):

Ultimately the behavior of entire societies towards biosphere must be transformed if the achievement of conservation objectives is to be assured. A new ethic, embracing plants and animals as well as people, which will be enable human societies to

live in harmony with the natural world on which they depend for survival and well-being.

The concept was thereafter introduced by Lester Brown (1981), who defined a sustainable society as one that is able to satisfy its needs without diminishing the chances of future generations. Later on, the Brundtland Report used the same definition to present the notion of sustainable development (WCED 1987, p. 229): “Human-kind has the ability to achieve sustainable development – to meet the needs of the present without compromising the ability of future generations to meet their own needs.” The definition does not mention the natural environment explicitly, focusing only upon human needs or wants. However, the report makes it clear that these “needs” include the conservation of the natural environment. The concept of sustainable development (Clark and Munn 1986) is an attempt to bridge the gap between environmental concerns about the increasingly evident ecological consequences of human activities and socio-political concerns about human development issues. In that sense sustainable development is a logical extension of arguments within the environmental literature of the 1960s, 1970s, and early 1980s. The concept of sustainable development carries within it the dynamic tension between poverty and environmental concern that is the most radical message of the Brundtland Commission.

Key Issues

The concept of sustainable development was introduced in the 1970s. It was firstly adopted and popularized as a world conservation strategy through the efforts of three influential conservation bodies – the International Union for Conservation of Nature and Natural Resource (IUCN) which has since been renamed World Conservation Union (WCU), the World Wide Fund for Nature (WWF), and the United Nations Environment Programme (UNEP) (Trzyna 1998). For the first time, the concept was mentioned in the Nature Conservation and Natural Resources Strategy of the International Union for Conservation of

Nature published by IUCN in 1980. Initially, it was associated with ecological sustainability, but it was soon used also to describe social and economic sustainability (Brown 1981). The greater popularity the concept gained through the Brundtland Report (WCED 1987) and Agenda 21 (UN 1993).

The Brundtland Report proposed “a global agenda for change” in the concept and practices of development. It presented new ideas such as equity and justice within and between generations, a shared understanding of the long-term goals for human life, collective action, and confidence in other people, new leadership, and governance instruments (WCED 1987). Agenda 21 was the document that was the culmination of the United Nations conference on environment and development, also known as the Earth Summit, held in Rio de Janeiro, Brazil, in 1992. This summit focused on ecological sustainability.

A few years after Brundtland report, Dobson (1996) identified more than 300 definitions and interpretations of the concept of sustainable development (p. 402). Later on, Klarin (2018) presented an overview of interpretations of sustainable development including the period 1987–2015. All definitions largely follow the core of the concept set out in the basic definition of the WCED (1987). In these definitions sustainable development is mostly perceived as a socio-economic system that enables human needs but also a long-term progress toward the well-being and improvement of overall quality of life in accordance with environmental constraints. Thus the principle of sustainable development focuses at the same time on humans living today and in the future.

The essence of the concept of sustainable development derives from the triple bottom line framework, which implies the balance between three dimensions of sustainability (Elkington 1994) (Fig. 1). Ecological (environmental) sustainability focuses on maintaining the quality of the environment which is necessary for conducting the economic activities and quality of life of people. So, human-environment interaction and impacts of one another belong to the ecological dimension (Spooner 1984). Social

Sustainable Development,

Fig. 1 Sustainable development and its dimensions (Dempsey et al. 2011; Elkington 1994; GRI 2013; Spooner 1984; Wolff et al. 2017)

sustainability strives to ensure human rights and equality, preservation of cultural identity, and respect for cultural diversity, race, and religion. Consequently, at the core of the social dimension are social equity and the sustainability of community (Dempsey et al. 2011). Economic sustainability is necessary to maintain the natural, social, and human capital required for income and living standards. Thus the **economic dimension** concerns the organization's impacts on the economic conditions of its stakeholders, and on economic systems at local, national, and global levels (GRI 2013, p. 67). The dimensions also integrate in a complex way; e.g., the political aspect is mainly a part of the economic dimension but also of the other two dimensions (Wolff et al. 2017).

The core of sustainable development includes three principles: eco-efficiency, inter- and intra-generational social justice, and participation in decision-making (WCED 1987). Eco-efficiency is striving to create more goods and services while using fewer resources and creating less waste and pollution. Inter- and

intra-generational social justice and possibility to participate in decision-making depend on many different aspects such as inter- and intra-generational equity, the distribution of power and resources, education, freedom, access to influential decision-making fora, general "capacity-building," etc. (cf. Basiago 1998; Bramley and Power 2009; Foladori 2005; Halme et al. 2004; Newell et al. 2004). The major theme included in these issues is the interconnection of degradation, poverty, and inequality. Fulfilling peoples' needs of the present and future generations requires actions that are of the short, medium, and long term. Basing on a long-term perspective, the sustainability approach incorporates an efficiency as well as an equity criterion, and it also emphasizes the need to maintain ecosystem health and integrity (Costanza et al. 1992).

Sachs (2015, p. XIII) has stated that "[S]ustainable development is both a way of looking at the world, with a focus on the interlinkages of economic, social, and environmental change, and a way of describing our shared aspirations for a

decent life, combining economic development, social inclusion, and environmental sustainability. It is in short both an analytic theory and a ‘normative’ or ethical framework.” The Brundtland Report clearly emphasized the link between the environment and development, as well as the importance of the human dimension in all decisions concerning environmentally sound development (Wolff et al. 2017). The importance of ecological sustainability lies in the fact that the society and economy depend on the integrity of the biosphere and the ecological processes taking place within it. Consequently, people should maintain social, cultural, and economic well-being without depleting natural resources or overloading nature’s delicate balance. According to UNESCO (2018): “Sustainable development cannot be achieved by technological solutions, political regulation or financial instruments alone. We need to change the way we think and act. This requires quality education and learning for sustainable development at all levels and in all social contexts.”

Education – A Crucial Precondition for Sustainable Development

Education for sustainable development is about enabling people to constructively and creatively address present and future global challenges and create more sustainable and resilient societies (UNESCO 2009). Learning in education for sustainable development often includes only knowledge, values, and theories related to sustainable development. However, it also means “[l]earning to ask critical questions; learning to clarify one’s own values; learning to envision more positive and sustainable futures; learning to think systematically; learning to respond through applied learning; and learning to explore the dialectic between tradition and innovation” (UN 2003). Thus it offers learners a context for developing active citizenship and participation (Berkowitz et al. 2005) (Fig. 2), embracing the complexity of the interdependencies of ecological, societal, and economic systems (Pigozzi 2007).

To understand sustainable development requires understanding of the behavior of systems

Sustainable Development,
Fig. 2 Active citizenship,
its dimensions, and
components (Mascherini
et al. 2009)

in general and of human and environmental systems in particular (Clayton and Radcliffe 1996). The overall goal of the UN Decade of Education for Sustainable Development (2005–2014) was to integrate the principles, values, and practices of sustainable development into all aspects of education and learning (UNESCO 2005; 2009). Based on a broad literature review, Wiek et al. (2011) propose five key competencies to be taken into account in education for sustainability. These competencies can be seen to support resolving sustainability problems in the real world through synthesizing the knowledge, skills, and attitudes. They are systems thinking competence, anticipatory competence, normative competence, strategic competence, and interpersonal competence. The competencies build upon one another and can be combined in different ways (Wiek et al. 2011).

According to Wiek et al. (2011), systems thinking competence means that people are able to understand the intermediate and root causes of complex sustainability problems. Systems thinking is a way of thinking that helps people see their role from a holistic point of view (Palmberg et al. 2017). Thus systems thinking is understood as the ability to see the world as a complex system where everything is connected to everything else (Draper 1993). It includes the capacity of identifying various biophysical and social components in a given environmental context and the interrelations in whole systems (Sterling 2003). It should therefore be based at least on critical thinking and reflection, deliberation, and action competence (Hoffman 2015). Draper (1993) associates seven thinking skills with systems thinking, structural, dynamic, generic, operational, scientific, closed-loop, and continuum thinking, whereas Stave and Hopper (2007) identify the same skills and several activities such as recognizing interconnections, identifying feedback, understanding dynamic behavior, differentiating types of flows and variables, using conceptual models, creating simulation models, and testing policies. System dynamics and systems thinking can be taught without involving sustainability, but sustainability cannot be taught without involving systems thinking (Cloud 2009).

Anticipatory competence is the capacity to think systematically about the future and future generations (Wiek et al. 2011) and to modify and shape the future of society and to guide its social, economic, technological, and ecological changes along the lines of sustainable development (de Haan 2006). This competence enables people to integrate concepts such as intergenerational equity and long-term consequences of present action into sustainability problem-solving.

Normative competence is the ability to understand concepts of justice, equity, social-ecological integrity, and ethics (cf. Moore and Nelson 2013). It means understanding how these concepts vary across and within cultures and how integrating these concepts contributes to solving sustainability problems.

The strategic competence is the ability to cope with unexpected problems, when no ready-made solutions are available (Mariani 1994). Interpersonal competence is the capacity to motivate and facilitate sustainability research and problem-solving. It requires communication, negotiation, and collaboration skills and expertise in participatory with stakeholders (Wiek et al. 2011).

Summary

Initially, the concept of sustainable development was associated with ecological sustainability, but it was soon used to describe social and economic sustainability, too. The greater popularity the concept gained through the Brundtland Report and Agenda 21. Sustainable development is mostly perceived as a socioeconomic system that enables human needs but also a long-term progress toward the well-being and improvement of overall quality of life in accordance with environmental constraints. The essence of the concept of sustainable development derives from the triple bottom line framework, which implies the balance between three dimensions of sustainability: ecological (environmental) sustainability, social sustainability, and economic sustainability. In the core of sustainable development are eco-efficiency, inter- and intra-generational social justice, and participation in decision-making. Thus to

understand sustainable development requires understanding of the behavior of systems in general and of human and environmental systems in particular because the ecological, social, and economic dimensions of sustainable development include several different aspects which are inter-related with each other.

Systems thinking is a way of thinking that helps people see their role from a holistic point of view. Systems thinking and systems dynamics can be taught without involving sustainability, but sustainability cannot be taught without involving systems thinking. Beside systems thinking, the capacities to think systematically, to understand ethical issues, to cope with unexpected problems, and also problem-solving and collaboration skills are needed when modifying and shaping the future of society in a sustainable way.

Sustainability is, thus, not only an environmental issue to be controlled by scientists, it is a multifaceted and interdisciplinary issue related to both local and global circumstances and past events as well as future prospects. There is a growing need for effective international cooperation to manage ecological, economic, and social interdependence. Thus the term sustainable development encompasses the concerns of people working in a wide range of disciplines from sociology to engineering, from geology to mathematics, not only today but also in the future.

Definition

The term sustainable development came into prominence in the Paris Biosphere Conference and Washington Ecological Aspects of International Development Conference held in 1968 (Barbier 1987). According to Beltratti (1987), sustainable development is a development that meets the needs of the present without compromising the ability of future generations to meet their own need.” Two macroeconomic terms development and growth usually thought to have a similar meaning. Growth refers to the percentage change in national income (NI), in more detailed the percentage change in the nation’s total value of final goods and services that are produced in a given time period. On the other hand, development indicates a rise in the quality of life for peoples’ well-being in a country. Life quality is often evaluated using a human development index (HDI), which considers personal factors not considered in economic growth, such as literacy rate, number of people per doctor, internet usage ratio, life expectancy, housing, educational facilities, medical services, the supply of food and poverty levels, etc. (Intelligent Economics 2019).

Theoretical Framework

The founders of modern economics including Adam Smith, Francois Quesnay, and Antoine Lavoisier consider the key issues in economic development. The early writings of economic development are traditionally based on human well-being (Sen 1988). In this framework, economists and policymakers focus on the enhancement of living standards. Bauer (1971) indicates that engineering and logistics tools help to solve this problem which may differ in developed and developing countries.

After the Second World War, economists (see Lewis 1955; Hirschman 1958) emphasize the interaction between economic growth and development. In the year 1950s modernization theories and structuralist development theories indicate

Sustainable Development Goals (SDGs), Table 1 Main economic development theories (1950s onwards)

Decade	Theory/Approach	Main idea
1950s	Modernization theories	European development model and international cooperation
	Structuralist theories	Southern part of the world needed to interact with the global economies.
1960s	Modernization theories	Resource intensity is higher in northern countries relative to southern
	Dependency theories	
1970s	Dependency theories	Basic human needs must be the priority in development
	Neo-Malthusian theories	Control on economic growth, population growth, and resource allocation
1980s	Neoliberalism	Macroeconomic policies should focus on the market
	Grassroots approaches	The role of local context and indigenous knowledge
	Sustainable development	Need to balance needs of current generation by considering future generations
1990s	Neoliberalism	
	Post-development	Eurocentrist and colonialist idea should be changed
	Sustainable development	Emphasize the role of cultural and social dimensions
2000s	Neoliberalism	Increased engagement with concepts of globalization
	Post-development	
	Sustainable development	
	Grassroots approaches	
	Right-based approach	

Source: Willis (2011). Theories and Practices of Development. p.28

that an increase in economic growth should enhance the quality of life and having economic growth without economic development is possible. A major revision on the concept of sustainable development arises in the 1970s which emphasizes meeting the basic needs by considering environmental issues (ILO 1976). In the late 1970s, empirical literature defines economic development as the functional achievement of a better life by the members of the society (Sen 1988). Today’s world, instead of economic activities, political, social, and cultural dimensions, as well as changes in the institutional framework, are the complementary elements of sustainable development. The below mentioned Table 1 provides the main development theories and their ideas in post-war era.

Sustainable Development Goals (SDGs)

Background and History

The sustainable development goals (SDGs) are rooted at the United Nations Sustainable Development Conference held in Rio de Janeiro in 2012. This implies of implementing

the new agenda – including how economic resources are mobilized to accomplish the sustainable growth agenda. Significant investment will be needed in both advanced and developing nations to attain the sustainable development goals (SDGs). This agenda will involve the mobilization in trillions of dollars of important resources. These funds do exist, however. In the globe, savings are far more than sufficient to fund the fresh agenda. It will be essential for us to achieve our goals on how to direct investments to promote sustainable development.

- Implementation and achievement will be based on and guided by countries’ own policies, programs, and plans for sustainable development. SDGs are a compass to align countries’ plans with their worldwide obligations. Their objectives are to be aligned.
- Sustainable development policies nationally and country-led will involve the mobilization of resources and funding.
- The fresh agenda should be made possible by all stakeholders: governments, civil society, the private sector, and others.

- In order to promote domestic initiatives, a revitalized worldwide partnership is necessary at a worldwide level.

In year 2000, SDGs replaced the millenium development goals (MDGs) which focus on the poverty. The MDGs give priority to objectives against extreme poverty, child mortality, hunger, deadly diseases such as HIV/AIDS, malaria, and at least primary education to all children. The UN announced that since 1990, child mortality, the number of out-of-school children, and HIV/AIDS diseases fell by about half.

Objectives

The traditional objective of sustainable development is ecological sustainability (Lele 1991). Sustainable development is aimed at creating and maintaining successful social, economic, and environmental systems. These systems are closely related: for their riches and safety, humanity relies on ecosystem services. In addition, beings can turn ecosystems into circumstances that are more or less desirable. Many ecosystem services are provided to humanity, such as clean water and air, food manufacturing, fuel, and others. Yet human intervention can make ecosystems unable to provide these services, with implications for human livelihoods, vulnerability, and safety. Such adverse changes are a loss of resilience (Folke et al. 2002).

For the well-being of its residents, economic development is the growth of the financial riches of nations, areas, or communities. From a political point of view, financial growth may be described by generating and/or keeping employment, promoting or increasing income and tax base as an effort to enhance the financial well-being and quality of life of a society. Development reduces individuals from low living norms to good jobs with adequate shelters. The decline of natural resources which may lead to pollution, congestion, and diseases are not taken into consideration in economic growth. However, development is about sustainability, which implies meeting current requirements without

jeopardizing future requirements (Intelligent Economics 2019).

The sustainable development objectives are the guiding principle for achieving a better and more sustainable future for everyone. The difficulties we face are worldwide: poverty, inequality, environment, environmental degradation, prosperity, peace, and justice (UN 2019).

Sustainable development encompasses three main areas:

- Governments' policies to fulfill wide financial goals, including price stabilization, elevated jobs, extended tax base, and sustainable growth. These attempts include monetary and fiscal policies, financial institution regulation, trade, and taxation policies.
- Infrastructure policies and programs and facilities, such as roads, parks, affordable housing, crime prevention, education, and initiatives.
- Policies and programs explicitly aimed at work creation and maintenance by particular company finance initiatives, marketing, neighbourhood growth, start-up, and growth of tiny enterprises, company growth.

In this framework, UN announced 17 SDGs:

- End poverty in all its forms.
- Zero hunger.
- Health.
- Education.
- Gender equality and women empowerment.
- Water and sanitation.
- Energy.
- Infrastructure and industrialization.
- Inequality.
- Sustainable production and consumption.
- Climate change.
- Ocean.
- Biodiversity, forests, and desertification.
- Peace, justice, and strong institutions.
- Partnership (UN 2019).

Sustainable development calls for concerted efforts to build a future for individuals and the

planet that is inclusive, sustainable, and resilient. In order to achieve sustainable development, the harmonization of three key aspects is critical: financial growth, social inclusion, and preservation of the environment. These components are interconnected and are all essential to personal and societal well-being. Eradicating poverty in all types and sizes is essential to sustainable development. In this context, sustainable, inclusive, and equitable economic growth must be promoted, higher opportunities for all must be created, inequalities reduced, living standards raised, social development and inclusion promoted equitably, and natural resources and ecosystems managed in an integrated and sustainable way must be encouraged (UN 2019).

Policies and Applications

The economic policies on sustainable development goals focus on the increase in human well-being over a long period of time. Until the Second World War, countries mainly implement regional strategies and development plans. In year 1944, 44 delegates from 44 countries met in Bretton Woods Conference to restructuring the global economies. During the conference, three main pillars International Monetary Fund (IMF), World Bank (WB), and General agreement of tariff and trade barriers (GATT, which becomes World Trade Organization (WTO)) were established. These international organizations also shaped the policies and agenda to achieve economic development. Since then, international cooperation began to play a key role in economic development. The UN system is the crucial organization among them.

The SDG fund is the first international cooperation to achieve SDGs. The fund and its joint programs in collaboration with 27 UN agencies, citizens, NGOs, and government agencies operated in 50 countries. Under the MDGs, steering, supervising, and implementing mechanisms arise in eight areas: children, food security and nutrition, gender equality and women's

empowerment, environment and climate change, youth employment and migration, democratic economic governance development, private sector conflict prevention and peace-building, and culture and development from 2000 to 2015 (UN 2020). On September 2015, the 2030 agenda titled "Transforming Our World: The 2030 Agenda for Sustainable Development" was formally adopted which includes the 17 sustainable development.

UN Global Goals

Definition

In 2015, the United Nations set the course for the transformation of the world toward global sustainability with its Agenda 2030. With the help of 17 Sustainable Development Goals (SDGs) as a framework and a total of 169 subgoals, states, institutions, companies, and civil society should be encouraged to work together for our future. The sustainability goals are intended to solve ecological, social, and economic topics. Nowadays the SDGs are increasingly finding their way into our everyday lives.

Introduction

On September 25, 2015, 193 member states of the United Nations adopted the so-called “Agenda 2030 for Sustainable Development” at the world summit at the United Nations headquarters in New York (UN, 2015). The Agenda 2030 today is the global framework for politics and is intended to perpetuate the tried and tested in terms of sustainability and at the same time initiate changes for a better future. Specifically, 17 Sustainable Development Goals (SDGs) were adopted with the Agenda, which came into effect on January 1, 2016, with a time frame of 15 years. The core messages are documented in the 30-page resolution of the United Nations.

With a view to the history of the agenda, it should be noted that the United Nations Conference on Sustainable Development in Rio de

Janeiro in 2012 lay the foundation for the sustainability goals. The subsequent consultation and development process resulted in the Agenda 2030. The adoption of the Sustainable Development Goals replaced the so-called Millennium Development Goals, which were valid until 2015. The Millennium Goals were a catalog of measures adopted by the international community in 2000 to combat poverty, secure peace, and protect the environment (UN, 2000). At the same time, the SDGs made a contribution to the adoption of the Paris Climate Protection Agreement in 2015, with which the international community advocated limiting man-made global warming.

The United Nations’ resolution on the Agenda 2030 defined 17 global Sustainable Development Goals (SDGs). The Agenda 2030 focuses on “five Ps” (people – planet – prosperity – peace – partnership) and thus covers a broad spectrum of sustainability aspects. For example, the SDGs focus on people to end poverty or hunger. The nation-states are determined to save and protect the planet, for example, by the efficient management of its resources. Additionally, all the people should live prosperous and fulfilling lives. Peace and freedom are other important goals, as well as the need to work together in order to achieve all the goals.

The sustainability goals are intended to solve ecological, social, and economic challenges. In addition – as the title of the resolution of the United Nations General Assembly claims – the “transformation” toward a more sustainable world should be ensured. The basic idea of focusing on a broad range of topics should help: from climate protection to education, from poverty and hunger to equal treatment, and from economy and employment to cooperative cooperation.

The resolution includes the preamble and a declaration by the heads of state and government as the basis for the Agenda 2030. It also includes the means of implementation and a focus on the role of global partnerships. And it includes information on measures for follow-up and monitoring in regard to the Agenda 2030. Finally, the resolution includes specific goals and targets. They are the heart of the Agenda 2030.

Sustainable Development Goals

SDG number	Title	Brief description	Number of subgoals/ targets
1	No poverty	End poverty in all its forms everywhere	7
2	Zero hunger	End hunger, achieve food security and improved nutrition, and promote sustainable agriculture	8
3	Good health and Well-being	Ensure healthy lives and promote Well-being for all at all ages	13
4	Quality education	Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all	10
5	Gender equality	Achieve gender equality and empower all women and girls	9
6	Clean water and sanitation	Ensure availability and sustainable management of water and sanitation for all	8
7	Affordable and clean energy	Ensure access to affordable, reliable, sustainable, and modern energy for all	5
8	Decent work and economic growth	Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all	12

(continued)

SDG number	Title	Brief description	Number of subgoals/ targets
9	Industry, innovation, and infrastructure	Build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation	8
10	Reduced inequality	Reduce inequality within and among countries	10
11	Sustainable cities and communities	Make cities and human settlements inclusive, safe, resilient, and sustainable	10
12	Responsible consumption and production	Ensure sustainable consumption and production patterns	11
13	Climate action	Take urgent action to combat climate change and its impacts	5
14	Life below water	Conserve and sustainably use the oceans, seas, and marine resources for sustainable development	10
15	Life on land	Protect, restore, and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss	12
16	Peace and justice strong institutions	Promote peaceful and inclusive societies for sustainable development, provide access to	12

		justice for all, and build effective, accountable, and inclusive institutions at all levels	
17	Partnerships to achieve the goal	Strengthen the means of implementation and revitalize the global partnership for sustainable development	19

Source: UN (2022)

The catalog of global Sustainable Development Goals (SDGs) comprises a total of 169 subgoals. The latter define specific goals or aim to provide financial resources and ensure the political and legal framework necessary to achieve the 17 sustainability goals. In this respect, the Agenda 2030 is not only about defining common goals, but also about describing the means that are necessary to achieve them.

The SDGs are essentially addressed to the nation-states. They therefore have universal validity. In particular, they apply regardless of the development status of a country. They are hence valid for developing countries and industrialized nations alike. However, regional and local levels are also addressed. Joint responsibility for global intentions can only be created through cooperation and a multistakeholder approach. That means the SDGs also call on businesses, science, and civil society beside legislators and politicians.

Details on the 17 sustainability goals and a total of 169 subgoals can be found on the website of the United Nations (UN, 2022).

In order to prevent the contents of the resolution from being vigorously pursued, a review framework was included in the Agenda 2030, which includes numerous measures and, with the help of (progress) reports, records the status of goal achievement. Statistical analyzes and

the Global SDG Indicators Database strengthen the monitoring. A set of a total of 232 indicators is used to record the implementation steps of the measures and to assess whether the goals have been achieved (Federal Statistical Office, 2022).

The SDGs are increasingly finding their way into our everyday lives. For example, companies rely on compliance with the SDGs and accordingly provide information in their annual reports. The sustainability goals are also gaining more and more attention in the perception of a general public as well as in marketing (Genders, 2021, p.68). Change processes have been demonstrably initiated, for example, through national sustainability strategies based on the sustainability goals. In order to have an overview of the progress toward achieving the SDGs, appropriate instruments have been developed – the so-called SDG Index with the corresponding reports offers a helpful overview (Sustainable Development Solutions Network and Bertelsmann Stiftung, 2022).

Nevertheless, there is also criticism: A study by the Basel Institute of Commons and Economics proves, for example, that the goals are not implemented equally; in particular, the goals of biodiversity, peace, and social inclusion are neglected in a comparison of all 17 goals (Basel Institute of Commons and Economics, 2019). And it has already been stated by heads of state and government that increased efforts are required to achieve the goals. The Global Sustainable Development Report (GSRD) confirms this view (UN, 2020). Not least based on these critics, international and national efforts – such as the Green Deal of the European Union in 2020 – have followed.

Summary

In 2015, the United Nations, set the course to transform the world. With the Agenda 2030, with the help of 17 Sustainable Development Goals (SDGs) and 169 subgoals, states, institutions, companies, and civil society are encouraged to create a more sustainable world. The

Agenda focuses on “five Ps” – people, plant, prosperity, peace, and partnership. By addressing all nation-states and their stakeholders, the SDGs are increasingly finding their way into our everyday lives and becoming the most important framework regarding sustainability.

Sustainability planning; Sustainable development; Sustainable planning; Three Es

Definition

Sustainable development (SD) is essentially a holistic design approach that takes into account both a community's inherent social characteristics and external interventions, the most important of which are the environment, politics, and economy. While this meta-approach includes a dangerous tendency to give way to an interpretation of “anything goes,” it is also the most common denominator in pursuing novel planning and development methods. Ensuring SD requires good planning first. SD planning can be defined as a process to chart a course toward the desired future of a community by all stakeholders and requires a political commitment of the local authorities to produce an action plan strategically for sustainable development and implement it. Its main objective is to ensure equality and justice between generations. Therefore, SD planning focuses on the problems of overconsumption and poverty and seeking solutions in the totality of social values adopting the search for development which is considered as a whole of economic, social, and ecological interactions – also defined as the three pillars of SD. During this process many obscurities arise as there is no general methodology for preparing SD strategic plans for local communities. As communities vary in their territory, environment, size, number of population, and political-social-cultural conditions, local authorities should find their own individual approach to this future together with their society.

Sustainable Development of Solar Energy

- Sustainability and Solar Energy

The main principles of SD planning require effective use of resources, activating local dynamics, supporting residents, and engaging internal potential should take a priority for the advantages of communities toward a sustainable future.

Background

SD is a broad umbrella term with no agreed-upon definition. Initially it is set out with environmental concerns, and in eliminating these concerns, the economic dimension has rapidly gained importance. At the first United Nations World Conference in Stockholm in 1972, economic development was offered to be handled with an attitude of using natural resources as effectively as possible by making the least possible impact on nature, and the term “ecological development” was firstly offered. In 1980, international environmental protection organizations and institutions declared the World Conservation Strategy which can be considered as a base for sustainable development.

SD entered the world agenda in the late twentieth century and became a global aim with the international agreements signed in the 1990s. The concept of SD was first described in 1987 in the Brundtland Report (Our Common Future) prepared by the World Commission on Environment and Development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” This is still the most widely used definition.

The UN Conference on Environment and Development, held at Rio de Janeiro on June 3–14, 1992, is an important step for the participating nations to adopt principles for environmentally responsive management. The Forest Principles have been accepted by an action plan Agenda 21 and Rio Declaration. The UN Framework Convention on Climate Change and the UN Convention on Biological Diversity have been opened for signature during the summit. The UN Convention to Combat Desertification, which was prepared in line with the decisions taken at the Rio Conference, was opened for signature in 1994.

In 2000, at the UN Millennium Summit, the Millennium Declaration and the Millennium Development Goals, aiming for 2015, have been determined by governments, and in line with a universal approach, the need for developing countries to work in cooperation with the developed countries was emphasized. Within the scope of ensuring environmental sustainability, integration of the principles of sustainable development into country policies and programs and reversing the loss of environmental resources, reducing biodiversity loss, and halving the proportion of the population without sustainable access to safe drinking water and basic sanitation were the main topics. On August 26–September 4, 2002, the “World Summit on Sustainable Development” was held in Johannesburg.

Twenty years after the Rio conference, the UN Sustainable Development Conference (Rio + 20 Summit) was held at Rio de Janeiro between June 20 and 22, 2012, and a roadmap called “The Future We Want” was issued as a result document. In this process, two main pillars of sustainability were defined, but it was soon understood that SD should be based not only on matching economic and environmental interests but also on guarantees of social justice in internal and international affairs. Therefore, society is the third pillar for SD.

On September 27, 2015, “Agenda 2030: UN Sustainable Development Goals (SDGs)” was set in New York as a continuation of the Millennium Development Goals. According to this, 17 targets and 169 sub-targets were adopted by 193 countries. Sustainable cities, climate change, drought fighting, and biodiversity conservation have been included in the agenda of SD. All these issues must be considered during the planning process.

Planning Process/Approach

Both new and developing communities require a model for continuing development, and the SD concept is one of the leading models for societal development with a wide consensus. Mebratu (1998) gives a historical review of the popularization of the concept in a small timeframe with help from diverse local and global organizations.

However, there are many different trends of thoughts on SD; Hopwood et al. (2005) create a framework for discussion by classifying and mapping various trends according to their political roots and attitudes toward change. Childers et al. (2014) discuss the challenges and opportunities of urban sustainability theory and its role in changing the urban environment, with particular emphasis on human well-being and environmental and social equity in terms of many perceived benefits of SD.

SD planning focuses on the problems of over-consumption and poverty and seeks solutions in the totality of social values. These values are identified in the “three pillars” of SD; environment, economy, and equality. In order to achieve sustainability, SD planning adopts the search for development which is considered as a whole in economic, social, and ecological interaction. Ensuring SD requires good planning first, and the success of the global implementation plan depends on country policies. Strategic development planning means a political commitment of the local authorities to produce an action plan for sustainable development and implement it. Implementation strategies should be developed, and SD principles should be determined in line with the sustainability policy carried out by a country. As communities vary in their territory, environment, size, number of population, political-social-cultural conditions, and the lifestyles, local authorities together with their society should find their own individual approach to SD. Therefore, local implementation plans should be prepared in line with regional development policies. Ensuring effective use of resources, activating local dynamics and internal potential should take priority for the advantages of communities. But during this process, many obscurities arise as there is no general methodology for preparing SD strategic plans for local communities (Čiegis and Gineitiene 2008). However, common basic principles such as “harmony with nature,” “livable built environments,” “place-based economy,” “equity,” “polluters share,” and “responsible regionalism” can be mentioned to evaluate local comprehensive plans (Berke and Conroy 2000). Besides “The Local Agenda 21 Planning

Guide has been prepared to assist local governments and their local partners to learn and undertake the challenging task of sustainable development planning” which puts forward a planning approach that will enable them to manage their cities, towns, and/or rural settlements in a sustainable way and create their own local action plans (International Council for Local Environmental Initiatives et al. 1996). Thus, SD planning can be summarized as “a proactive process that allows the local government and its partners to support and engage the intellectual, physical, and economic resources of residents to chart a course toward a desired future” (International Council for Local Environmental Initiatives et al. 1996). This multidisciplinary point of view plays an essential role in shaping the future development of a region.

SD planning process involves some phases (look at Fig. 1), and analyzing the conditions is the first step for generating a sustainable vision for a community. With this vision the stakeholders, institutions, governmental organizations, and interest groups that will support the process can be clarified, and strategic goals of the community can be defined realistically. The “planning group” has to be “formed in accordance with the principles of democracy and readiness to spend time for their community” (Čiegis and Gineitiene 2008). After the determination of vision through the

Sustainable Development Planning, Fig. 1 Phases of sustainable development planning

analysis phase, the planning process begins, and the activities/tasks are defined together with their responsibilities, timetable, and budget to create an infrastructure for implementation and monitoring. The success of the implementation phase depends on the analytical framework constituted during the planning phase, and managing access to finance is crucial. Accurate documentation of the implementation activities and their impacts should be provided from the beginning of implementation. Monitoring process and reporting are important when considering new and emerging challenges while ensuring continuity. The feedback phase ensures accountability among stakeholders and informs the public about the progress and the changes so that all the actors can adjust their own actions and behaviors (International Council for Local Environmental Initiatives et al. 1996). Moreover, in case of a failure, the feedback mechanisms ensure that the problems in the action plan are identified, reanalyzed, and corrected. Afterward, the circularity in the process triggers further analysis according to the new situation, and SD planning begins again.

Given the overwhelming amount of available possibilities, the decision-making process is complex; thus, a number of tools were created to help establish what is most essential for a community by simplifying theoretical, social, and practical problems (EASAC 2005). There are two main approaches to SD planning: “bottom-up” and “top-down.” In the top-down approach, strategic plans are prepared by foreign or local experts. The plans developed by foreign experts are often unrealistic and are far from being implemented (Čiegis and Gineitiene 2008). Therefore, it is more accurate for foreign and local experts to work together. However, in all circumstances, the opportunity for the public to participate in preparatory planning and implementation processes can be very small. Therefore, it is difficult to provide a truly participatory process. Local authorities need to address this issue separately and make extra efforts to ensure active participation. But the basic advantage of bottom-up approach is the possibility to concentrate on the main problems and the solutions through the eyes of local people with a better knowledge of the present situation. Therefore, SD

planning is also important in terms of achieving strategic management through community participation. The participation and cooperation between public, private, and nongovernmental actors are planned for in local and regional development policies.

Key Issues

Some issues of SD can be forecasted and modeled, while some are more difficult to predict. SD planning embraces many aspects of sustainability in one way or another. Yet a SD planning problem does not have only one answer; therefore, there are many issues to consider and discuss. What is SD? Who gets to decide what SD is? What does SD look like? What are the key sustainability aspects that shape a plan? What kind of a plan will be implemented? How will it be implemented? When do the various stakeholders involved have any say in the process (Tokuç and Güller 2018)? All these questions have numerous answers depending on the type, size, and location of the project and the involved stakeholders; meanwhile SD planning provides the roadmap. Although SD planning depends on the integration of the pillars of SD within a holistic view, most of the current debates stem from their local interpretations for the decision process. Therefore, the following paragraphs take a separatist view of the pillars to allow a deeper discussion of the relevant issues.

Economic

Economy mainly deals with achievement of local development goals, job creation, and development of infrastructure. Energy and resource issues are also linked to economy with emphasis on building circular cities, economies, and production chains (European Commission 2015). Blue, green, or blue-green circular economies and growth mechanisms including degrowth are strategies that can sustain the natural life, while ensuring humanity is a part of the ecological system. Actions related to construction such as mobilizing vacant lots and buildings, renovating existing buildings and facilities, utilizing prefabricated

and mass-customized designs are all relevant research topics that also have the potential to create green jobs. Sustainable consumption and production of high-value assets in accordance with development goals should be given priority, where the definition of value is important. The assets have to be managed via the use of cost-effective and economically viable technologies and sustainable, resource-efficient and low-carbon business models.

Energy efficiency, utilization of natural or local energy resources, energy demand management, infrastructure, and energy management regulate the communities' relationship with the other communities. Waste management models can be imitated from nature. Management of assets and infrastructure can be integrated with technologies like smart meters and concepts like smart cities. Developments in smartness and their integration into various application areas are being investigated (Höjer and Wangel 2015). Public procurement mechanisms play a role on their implementation. Access to emerging or mature technologies, size of the development, and tourism potential effect a settlement's carbon footprint and related roadmap proposal to SD. Initiatives like slow food or ecotourism and incentives can either help or hamper efforts on availability and public acceptance. For instance, successful eco-destination marketing can make a community grow in an undesired direction and decrease the sustainability of the natural assets, thus creating and maintaining sustainable management protocols are crucial.

Social

The *social* dimension of sustainability is not clearly defined, and a number of physical and nonphysical factors can be identified in relation to social domain. Poverty, hunger, gender, age, disability, health, accessibility, resilience, immigration, emigration, refugees, and effects of natural disasters including climate change are all topics under the heading of the term social sustainability. Murphy (2012) reviewed the social pillar of sustainability and proposed four overarching concepts, which are public awareness,

equity, participation, and social cohesion. The built environment is a significant indicator of a community's sociocultural quality and level of development. The rise in environmental consciousness either individually or collectively can be seen in all of the phases of SD planning, including the making of legislation. The preferred approach in SD planning is participatory planning, where pluralism is at the core. Sociocultural values of a community, the community's relationship with its habitat, and the outlook of its local authorities are some of the most dominant indicators. All of the stakeholders can participate in SD planning, while the main actors include the community and governing bodies. Governments and structure of local governance also play an important role since public involvement in the planning process can be difficult when the dialog between the society and local authorities is weak. Institutions also play a role in sustainable communities as participants. While there are only three publicly accepted pillars of SD, nowadays some researchers are searching for perspectives that make it easier to define specific policies toward SD. In this context, sometimes other aspects of society such as culture (Hawkes 2001) institutions (Čiegis and Gineitiene 2008), governance, or policies can be cited as a fourth pillar (look at Burford et al. 2013). Meanwhile, Seghezze (2009) defines the five dimensions of sustainability as three dimensions of space (place), time (permanence), and human (persons) dimension.

Environmental

At its beginning, SD was concerned with mainly environmental concerns including air, water, and soil pollution, degradation of ecosystems, climate change, resource depletion, and waste. The energy, water, and food nexus are one of the greatest challenges of humankind and a principal aim of SD planning. Poor planning can lead to increasing energy and resource consumption and unsustainable changes in land use especially loss of areas necessary for food production and biodiversity. Poor planning also may cause urban problems such as heat island phenomena, river and coastal flooding, poor indoor air quality, and

environment-related health issues. SD planning can make use of ecosystem services so that the water cycle, water quality, soil quality, stability, erosion, air quality, and noise quality can be regulated and improved. For example, vegetation, soil, and vegetables in green ecosystems and water in blue ecosystems capture and sequester carbon inside while also improving air quality. From another point of view, planetary stability can be among the goals of SD; in this context Griggs et al. (2013) propose some provisional targets for SD in 2030.

SD for climate change adaptation and mitigation requires lowering environmental impacts. There are a number of strategies; therefore decision-making and using tools are also taking energy-water-food nexus which is critical (for further discussion, look at Bieber et al. 2018). One of the most common approaches for resource conservation and planning is life cycle assessment. The carbon emissions resulting from energy consumption in buildings and their role in environmental problems are evident. Yet the embodied emissions of construction, operational emissions, and emissions from changes in land coverage cause global environmental concerns. Therefore, changing ways of building and creating nature-based and circular systems that support urban ecologies are ways for SD planning to enhance sustainable urbanization. Population density, urban community amenities, land coverage, interventions in the public space, transportation, utilizing blue and/or green infrastructure, and zero waste are among the tools of SD planning. In addition, edible city solutions and urban gardens can also help with the issues of territorial coherence and biodiversity.

Summary

“How should a community develop in the future?” is a valid research question within various fields to find alternatives to unsustainable ways of living. However, the vast numbers of opportunities inherent in SD make a number of futures possible; thus, another question becomes

inevitable: “How is a community supposed to choose between so many options?” Concepts such as solar, eco, sustainable, green, etc. are being researched with many small-scale implementations; however, the difficulty of adapting an existing society to a concept that was never thought during its design is inevitable. After many excellent studies, implementations, and legislations, there are still many uncertainties. The main challenge is how to balance the conceptual coexistence of environment, society, and economy in the planning dimension. There is no general agreement on how the concept should be translated into practice. To implement economic instruments aligned with environmental goals and the societal values is not simple. In this process, sometimes some of the principles may be emphasized more and overshadow other principles. However, sustainability can be promoted by a plan only if all the values are represented.

The two main approaches of SD planning are “bottom-up” and “top-down.” The UN is the most significant actor in the global SD debates, therefore the “top-down” approach. It gives direction by forming goals (such as millennium goals or sustainable development goals), creating supporting programs, and providing funds and intergovernmental agreement frameworks. For instance, its effect can be seen on the concept of resilience. Studies on resilience were very few in number before it became part of the description of SD goal 11; afterward they rose in number. Reaching resilience is a key planning aim in urban hazard planning and can be utilized in dealing with many problems of SD. Moreover, international awareness is very high, and many countries have their own development plans, and ensuring their sustainability takes priority. An indicator of the importance of planning is that most investors analyze strategic development plans when choosing a place for the investments.

The local actors play the main part in the “bottom-up” approach. In the last decades, environmental consciousness became embedded in the social norms of many countries, from their legislation to their way of doing business. Conscious individuals, who demand a say in the

decision process, work to put many issues on the table and to implement many practices. The most common planning methods are design by the governing authority, tenders, colloquia, and design competitions. Since continuous improvement in the desired direction is an aim of sustainable communities, public involvement is also a necessity. However, public involvement into the planning process can be difficult if there has been no preceding social participation tradition before or if the society is passive or negative against the local authorities.

Both traditional and innovational design approaches that look at the nature as an inspiration or a teacher became widespread, while new multidisciplinary areas of research such as biodesign and circularity are increasing technical knowledge. A SD strategic planning roadmap can be created by comparatively analyzing good practices in different communities. Rather than separate systems, all of the pillars should be holistically designed both to ensure equality and justice between generations and to provide a livable sustainable development. Thus, there is not a single definition of SD planning, but rather there are a number of approaches that enable the involvement of many issues (i.e., pillars) at the same time while balancing both local values and global priorities.

Sustainable Dialogue

Andrea Venturelli and Simone Pizzi
Università del Salento, Lecce, Italy

Synonyms

[Stakeholder engagement](#)

Definition

The concept of dialogue was introduced for the first time by Plato, meaning “an exchange of opinion between two or more people” (Khan 1998). From an etymological point of view, it stems from the Greek διάλογος (*dialogos*, conversation). “Dialogue” has been widely analyzed in business and management studies because of firms’ need to engage in an effective way with their internal and external stakeholders. Furthermore, the increasing growth of new financial and nonfinancial reporting frameworks has extended academics’ interest in this field of study. Nowadays, dialogue represents a central topic in discussion about the achievement of the United Nations’ Sustainable Development Goals (SDGs). Specifically, SDG 12.6 requires the wide diffusion of nonfinancial reports in order to increase dialogue between stakeholders. Furthermore, the World Development Business Council for Sustainable Development (2002) defines stakeholder dialogue as “a powerful catalyst for change. It promotes greater transparency; information sharing and inspires society to work together.”

Corporate Communication: A Brief History

Over the past few years, several changes have occurred in the form and substance of communication from firms (Ihator 2004). These changes have been influenced by the increasing attention

from stakeholders on firms' activities. From a formal point of view, these paradigm changes have been supported by the wide diffusion of new tools like nonfinancial reports, social media, and forums. On the other hand, the increasing attention paid by business stakeholders to sustainable development has impacted the content of communication (Pizzi et al. 2021). This now includes both the disclosure of financial results and non-financial information. Furthermore, some firms have started to integrate their financial and nonfinancial information in a standalone report (Eccles and Krzus 2010). However, the concept of dialogue is different from the disclosure of information through a one-way tool. Instead, an effective dialogue consists of a 2-way exchange of information between firms and stakeholders.

From Corporate Communication to Corporate Dialogue

Effective dialogue with internal and external stakeholders can increase firms' perceived legitimacy (Greenwood 2007). An increasing number of academics have tried to identify the theoretical framework that will be most useful to analyze this phenomenon. However, currently only a small proportion of studies are truly oriented to analyze stakeholder engagement through the lens of effective dialogue.

The relationship between legitimacy and stakeholder engagement is one of the most important subjects debated in CSR-related studies (Schuman 1995; Claasen and Roloff 2011; Bonson and Ratkai 2013). Prior literature suggests how firms' implementation of CSR activities could be analyzed through the perspective of signaling theory (Hetze 2016; Zerbini 2017). In fact, the traditional approach of signaling theory (Spence 1973) regards the market competition between firms, who transmit "signals" that cause consumers to perceive different levels of quality (Bergh et al. 2014). From the perspective of CSR communication studies, this traditional approach is extended

to the reputational effect (Patten 1991). However, the achievement of reputational benefit from CSR communications is not easy for firms due the possibility of sending messages that are irrelevant to the intended audiences (Hetze 2016). For effective communication, it is necessary to analyze the composition of the audience and their expectations of the firm's activities (Du and Vieira 2012).

The New Paradigms of Corporate Dialogue

Nowadays, an increasing number of firms have started to engage with their stakeholders through new tools such as Facebook, Twitter, and LinkedIn. However, only a few studies have analyzed this new form of accountability. Studies about social media communication are generally based on the dialogic principle defined by Kent and Taylor (1998) regarding the use of institutional websites. In this theory, "dialogue" is defined as any negotiated exchange of ideas and opinions characterized by an honest, open and ethically based give and take (Bortree and Seltzer 2009). The use of social media to build a positive attitude allows the company to identify the stakeholders and gives them the chance to satisfy them and the possibility to engage with them over a long period of time (Unerman and Bennet 2004). Also, the possibility for users to give negative feedback to the signal could be an efficient driver to minimize the risk of greenwashing by the firms' management (Lyon and Montgomery 2013). In fact, a too-proactive approach by the firms could be perceived by stakeholders as a greenwashing strategy (Aji and Sutikno 2015). Previous studies suggest how the use of social media tools in the strategic communication of firms, through the analysis of big data, has increased the degree of interaction between them and the stakeholders (Ma 2014; Gunther et al. 2017). However, stakeholder engagement through social media could be characterized by different degrees of information delivered and exchanged. Specifically, it could be characterized by two different approaches. The

first approach consists of a monologue by the firm about a specific topic (Brainard and Edlins 2015; Swani et al. 2014). The second approach is a two-way dialogue between firms and stakeholders, and it is most common in email and website communications (Lattimore et al. 2004).

Summary

In the current scenario, the achievement of effective dialogue with stakeholders represents one of the most important challenges for managers. It has become a necessity because of the increasing attention paid by stakeholders to new themes related to the concept of sustainable development. However, engaging in an effective way with stakeholders can be highly complex. Firms have started to introduce new items in their communication strategies to shift from a “monologue” to a “dialogue.” The use of new tools like social media to engage effectively with stakeholders in dialogue about nonfinancial themes will be the next challenge for worldwide companies.

Growth

Definition

The sustainable growth rate (SGR) is the maximum rate of growth that a company can sustain without having to finance growth with additional equity or debt. The SGR involves maximizing sales and revenue growth without increasing financial leverage. In a firm level, a sustainable rate of growth is the maximum growth rate that a firm is able to maintain without raising the fund flow. For a small company owner, the rate is how much more money he can collect each year without investing his own money or borrowing from the bank. Both small and big business owners should calculate their sustainable rate of growth to determine whether their capital is adequate to meet their strategic needs for growth (Higgins 1981).

Sustainable economic growth means a rate of growth that can be maintained, especially for future generations, without causing other important economic problems. There is a compromise between current rapid economic growth and future growth. Today, rapid growth may exhaust resources and cause environmental problems to

future generations, including oil and fish depletion and global warming (Daly and Townsend 2003).

Measuring Growth

Growth can be evaluated in the light of a general trend as an annual rise in real GDP. The lengthy term noninflationary average economic growth rate is the trend rate of growth (Economics Online 2019). If growth increases substantially above or below the trend, excessive growth or low development will occur in the economy. The economic downturn or recessions take place if the rate is negative for two quarters or more in a row. Therefore, standard growth potential estimates that view inflation as the only indicator of macroeconomic disequilibrium, together with inflation stability, have supplied the policymakers with false signals. This article presents an alternative to prospective growth methodology to achieve viable growth rates. Sustainable development is described as a development of production which, through a broad variety of national and external factors, does not produce or expand macroeconomic imbalances (Alberola et al. 2013).

In the majority of countries, even the UK, GDP is the formal basic metric of production utilized. Gross measurements record the total cost of all products and services, including equipment bought as a substitute for current equipment. Capital substitution is referred to as capital use or decrease. Net production is an alternative to aggregate output. This means that depreciation is taken into consideration and deducted from the gross values. Revenues from property relate to revenues generated through different kinds of foreign investments such as earnings and dividends. When added, the measure is transformed into a domestic item known as the GNP.

Business is considered in the modern world as the chance to create wealth, financial prosperity, and employment. Market economies, however, depend on the organization's integrity to operate within societal values and norms (Kanji 2007). When real output increases over time, economic growth occurs. Gross Domestic Product (GDP) measures the real

output at constant prices, thereby eliminating the impact of price increases on national value output. Growth periods are often triggered by an increase of aggregated demand, such as an increase in consumer expenditure. Any extra demand will push the price level up if production does not increase.

Inclusive Sustainable Growth

The assistance of the United Nations Development Programme (UNDP) for sustainable and inclusive development enables individuals to contribute to financial development and profit from it with minimal environmental impacts. We think it helps to bridge the financial, social, and environmental gaps for viable development by generating circumstances for inclusive growth. The United Nations (UNDP) works widely with other United Nations organizations and development actors including IFIs (International Financial Institutions), private foundations, the private sector, and civil society to help nations in pursuing inclusive and sustainable policies for growth. The three broad policy priorities that frame UNDP's support to achieve inclusive and sustainable growth are as follows:

- Inclusive- and sustainable-growth-integrated planning. Activities include developing evidence-based domestic plans assessment, supporting financial diversification and sustainable development, and efficient management of natural resources.
- Promoting job development, decent labor and redistributive poverty, and inequality and exclusion programs. Activities include encouraging decent job, removing obstacles to accessing employment possibilities, enhancing working circumstances, and expanding redistributive programs in particular in support of schemes of social security.
- Mobilizing and expanding the funding to enable an inclusive and sustainable development transition. Activities shall include encouraging fiscal policies that are compliant with viable and inclusive development targets; encouraging the mobilization of national

resources and the implementation of innovative environmental and clean power funding systems (UNDP 2019).

In designing macroeconomic policies, the notion of future development plays the main role. Monetary, fiscal, and recent strategies take into consideration estimates of output gaps – the distinction between perspective and observed output – to adjust their position to decrease possible macroeconomic imbalances, thus damping overall changes. Prospective development in theoretical and empirical literature has received comprehensive analyses, yet two variables influence the significance and utility of these ideas for economic policy. First, there is the capacity to reflect and synthesize economic imbalances. Second, there is the extent to which the estimates of the production gap and their strength toward new data remain uncertain (Alberola et al. 2013).

The notion of perspective development is based on many of the methodologies employed to achieve trend growth rates. In the context of manufacturing, the traditional Phillips curve is used to estimate standard future development connecting unemployment to inflation. Consequently, these estimates of future development only consider one specific imbalance: inflation. A reevaluation of sustainable growth levels is therefore needed to eliminate the imbalances that the economy entails in expansionary stages (Alberola et al. 2013).

Summary

As an economic term, growth refers percentage change in NI-National Income which the total value of all the final goods and services produced in a country for a given time period. Sustainable growth rate may indicate a rate of growth which macroeconomy or economy as a whole expect to experience without creating any volatility or imbalances.

Sustainable Education

Eila Jeronen
 Faculty of Education, University of Oulu, Oulu, Finland
 Faculty of Educational Sciences, University of Helsinki, Helsinki, Finland
 Faculty of Education, University of Lapland, Rovaniemi, Finland
 Tampere, Finland

Definition/Description

The concept of sustainable education is based on the terms sustainability and education. The term “sustainability” is derived from the Latin word *sustinere* and the term “education” from the Latin word *educatio*. The former is a model of

thinking in which the quality of life is improved through balancing the environment, society, and the economy (Jeronen 2013). The latter refers to an activity or process for acquiring or sharing knowledge or skills, developing the powers of reasoning and judgment, and intellectually preparing oneself or others for life (Thesaurus 2021). Many of today’s challenges require a veritable shift in thought and behavior to support sustainable living. According to Stephen Sterling (2008), the necessary cultural change can be achieved through sustainable education (SE). He defines the concept as:

a change of educational culture, one which develops and embodies the theory and practice of sustainability in a way which is critically aware. It is therefore a transformative paradigm which values, sustains and realises human potential *in relation to* the need to attain and sustain social, economic and ecological well being, recognising that they must be part of the same dynamic. (Sterling 2001, p. 22)

The concept of SE thus refers to finding sustainable solutions to environmental, social, and economic problems through education (Prabakaran 2020). It is a concept that challenges both formal and non-formal educational sectors to actively participate in the creation of economic, social, and environmental programs that improve quality of life, increase empowerment, and respect interdependence (Abduganiev and Abdurakhmanov 2020).

Introduction

Our machines, our value systems, our educational systems will all have to be informed by (the) switch, from the machine age when we tried to design schools to be like factories, to an ecological age, when we want to design schools, families and social institutions in terms of maintaining the quality of life, not just for our species, but for the whole planet. (Cited in Sterling 2008, para. 5)

Since the 1980, there has been increased international attention on sustainability and sustainable development (SD) issues. According to UNESCO (United Nations Educational, Scientific and Cultural Organization), the difference between the two concepts is that sustainability is a long-term

goal toward a more sustainable world, whereas SD implies the processes to reach this goal (UNESCO 2018a). Sustainability can be considered as a paradigm for thinking about the future in which environmental, societal, and economic considerations are balanced in the pursuit of an improved quality of life (Jeronen 2013). It is heavily context-dependent in social, cultural, and environmental situations (Kopnina 2012). Brundtland's report (1987) defines sustainability as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (UN 2021a, p. 1). Today, it is described as the organizing principle of human development that fulfils long-term needs of humanity and at the same time sustains the "ability of natural systems to provide natural resources and ecosystem services upon which society and economy depend" (Glavić 2020, p. 2). It is thought to comprise three main dimensions: the ecological, social, and economic dimensions (Fien et al. 2009; Quinn et al. 2016). These dimensions are complexly interrelated. Also research and education of sustainability are based on these dimensions (Maurer and Bogner 2019).

To promote sustainability locally, regionally, and globally, United Nations (UN), including the UN Department of Economic and Social Affairs, with several countries began to develop sustainable development goals or global goals (SDGs). In June 1992, in Rio de Janeiro, Brazil, more than 178 countries ratified Agenda 21, which aimed to work together globally to improve people's lives and protect the environment from an SD perspective. At the September 2000 Millennium Summit in New York, the Member States adopted the Millennium Declaration, which led to eight Millennium Development Goals (MDGs) of reducing extreme poverty by 2015. The Johannesburg Declaration on SD and the Plan of Implementation, adopted in 2002, reaffirmed the global commitments to poverty eradication and environment through multilateral partnerships, based on Agenda 21 and the Millennium Declaration. In June 2012, the UN Conference on Sustainable Development (Rio + 20) in Rio de Janeiro, Brazil, adopted "The Future We Want."

Among other things, it decided to develop a set of SDGs to build upon the MDGs. Negotiations on a Post-2015 Development Agenda began in January 2015 and ended in August 2015. The negotiations resulted in the adoption of the Addis Ababa Action Plan in July 2015. The final document, *Transforming Our World: The 2030 Agenda for Sustainable Development* (called Agenda 2030), with 17 SDGs at its core, was adopted at the UN Sustainable Development Summit in September 2015 in New York (UN 2021b). Today, the Division for Sustainable Development Goals (DSDG) supports capacity building on the SDGs and related thematic issues.

The 2030 Agenda for Sustainable Development and its 17 SDGs are focused both on environment and a multidimensional approach to SD to achieve the well-being of people around the world (Di Fabio 2017). The 17 SDGs are: (1) no poverty, (2) zero hunger, (3) good health and well-being, (4) quality education, (5) gender equality, (6) clean water and sanitation, (7) affordable and clean energy, (8) decent work and economic growth, (9) industry, innovation, and infrastructure, (10) reducing inequality, (11) sustainable cities and communities, (12) responsible consumption and production, (13) climate action, (14) life below water, (15) life on land, (16) peace, justice, and strong institutions, and (17) partnerships for the goals (UN 2016).

Each SDG typically has 8–12 targets, and each target has 1–4 indicators to measure the achievement of the objectives. The targets are either "outcome targets" (conditions to be achieved) or "means of implementation." SDG17 concerns how the SDGs can be achieved (Bartram et al. 2018). The Inter-Agency and Expert Group on SDG Indicators (IAEG-SDGs) developed a Global Indicator Framework for SDGs. It was adopted by the General Assembly in July 2017. The indicator framework will be refined annually. It was reviewed comprehensively by the Statistical Commission in March 2020 and will be reviewed again in 2025. The global indicator framework will be complemented by indicators at the regional and national levels, which will be developed by Member States (see UN 2016).

Targets and Indicators of SDG4

Education as an SDG is, perhaps more than ever, a priority to ensure that students are able to develop appropriate and rapid responses based on inputs to the SDGs. The SDG4 called “Quality Education” particularly focuses on ensuring inclusive and equitable quality education and promoting life-long learning opportunities for all. It aims to “ensure inclusive and equitable quality education and promote lifelong learning opportunities for all” (UNESCO 2017).

The SDG4 includes seven targets that stress inclusion, quality, and equality in all phases of education. The first three targets aim to ensure that all children and adults have access to quality education from early childhood to primary and secondary education and to vocational and university education. The fourth target is to improve the working capacity of young people and adults. The fifth target addresses access to education for people with disabilities, indigenous peoples, and vulnerable people. The sixth target aims to guarantee literacy and numeracy for all young people and to reduce adult illiteracy. The seventh target concerns the content of education aiming to develop the knowledge and skills needed to promote SD, gender equality, and peace and non-violence culture (Unterhalter 2019).

The 32 indicators related to these targets are classified into Tiers 1, 2, and 3 (UN Statistical Commission 2018). Only two indicators are classified as Tier 1: participation in organized learning 1 year before primary school and the amount of official development assistance spent on higher education scholarships. The Tier 2 indicators relate to the methods used to try to achieve the targets. Many of the Tier 3 indicators are linked with facets of quality and equality (Unterhalter 2019). One indicator (the indicator 4.7.1) addresses the extent to which global citizenship education and education for sustainable development (ESD) should be taken into account in national education policies, curricula, teacher education, and student assessment (UN 2016, p. 5).

Several different concepts have been and continue to be used in education of sustainability and

SD. The concepts do not necessarily mean the same thing, even if they contain similar ideas. In the following sections, these concepts are considered separately from the perspectives of education, teaching, and learning.

Concepts Related to Sustainability Used in Education

The concepts “sustainability education,” “education for sustainable development,” “education for sustainability,” and “sustainable education” are often used as synonyms. However, they do not necessarily mean the same thing although they do contain similar ideas (Table 1).

Sustainability education has evolved in waves in the twentieth century in response to sustainability challenges (Wals and Blewitt 2010). The first wave, called environmental education, paved the way for a new type of educational culture. The first descriptions of it were published at the Intergovernmental Conference on Environmental Education in Tbilisi (UNESCO 1977). In Agenda 21, it has been stated that environmental education is a continual, life-long learning process to raise public awareness and action globally, nationally, and locally in every area in which humans impact the environment (UN 2003). The main theme was thus concerned about the state of the environment. The 1992 UN Conference in Rio Janeiro emphasized the need to integrate environmental education and development (UN 1993). This integration gave birth to four new waves of sustainability education. The first of these waves was about implementing environmental education and the related environmental education for sustainability (EefS) in response to environmental and developmental concerns (Papenfuss et al. 2019). The key components of the EefS are relevance, integrity, values, action, and political literacy (Tilbury 1995). Thus, the EefS evolves by acknowledging that sustainability challenges are socially connected, transdisciplinary, normative, and urgent.

The second of the new waves, called the campus greening movement, addressed the complicity in sustainability dilemmas (Wals and Blewitt 2010).

Sustainable Education, Table 1 Definitions of the concepts “sustainability education,” “education for sustainable development,” “education for sustainability,” and “sustainable education”

	Definition	Source
Sustainability education	An interdisciplinary, collaborative, experiential, and potentially transformative process of creating a space for inquiry, dialogue, reflection, and action about the values and goals of sustainability	Moore (2005, p. 78)
Education for sustainable development (ESD)	Holistic and transformational, lifelong learning process which aims to enhance the cognitive, social, emotional, and behavioral dimensions of learning	UNESCO (2020)
Education for sustainability (EfS)	Regarded as possessing both the <i>process towards</i> and the <i>vision of</i> sustainability	Wade (2008, p. 32)
Sustainable education (SE)	A change of educational culture, one which develops and embodies the theory and practice of sustainability in a way which is critically aware. It is therefore a transformative paradigm which values, sustains and realises human potential <i>in relation to</i> the need to attain and sustain social, economic and ecological well being, recognising that they must be part of the same dynamic	Sterling (2001, p. 22)
	A change of educational culture which both develops and embodies the theory and practice of sustainability in a way which is critically aware. This would be a transformative paradigm which values, sustains and realizes human potential in relation to the need to attain and sustain social, economic and ecological Well-being, recognizing that they are interdependent	Sterling (2003, p. 233)

It focuses less on pedagogy, and more on efforts to reduce ecological impacts. However, despite the development of the first and second new waves of sustainability education, many indicators of global sustainability continued to decline during the 2000s (Rockström et al. 2009).

The aim of sustainability education was to meet these new challenges with the help of the third new wave, which included transformative and emancipatory pedagogies and their interaction (Papenfuss et al. 2019). It aims at “learning that helps people transcend the ‘given,’ the ‘ordinary,’ and often the ‘routine ways of doing,’ to create a new dynamic and alternative ways of seeing and doing” (Wals and Blewitt 2010, p. 66).

The fourth new wave of sustainability education can be considered contemplative education (Papenfuss et al. 2019). It has been defined as a “way of knowing that compliments the rational and the sensory” (Hart 2004 p. 29), and “a set of pedagogical practices designed to cultivate the potentials of mindful awareness and volition in an ethical-relational context in which the values of personal growth, learning, moral living, and caring for others are nurtured” (Roeser and Peck 2009, p. 11). Other goals are the development of

empathetic connection, compassion, creativity, and altruistic behavior (Zajonc 2013).

In summary, it can be stated that, over the years, sustainability education expanded from an original ecological perspective to include social, ethical, and transformative aspects as well.

The use of the concept ESD became more widespread during the United Nations Decade of Sustainable Development (2005–2014, DESD) (UNESCO 2009). The Decade was the culmination of many initiatives that have developed on the international stage since 1980, when the concept “sustainable development” was first introduced by Robert Prescott-Allen (IUCN 1980). Very recently (UNESCO 2018b), ESD is placed at the center of the 2030 Agenda for Sustainable Development and has been widely acknowledged as a key enabler of all 17 SDGs (besides SDG4 Quality Education for all). ESD is one of the teaching approaches with the complexity of a globalized world. The key principles of ESD are (UNESCO 2009, 2017):

- A transformative and reflective process that seeks to integrate values and perceptions of sustainability into, not only education systems,

but one's everyday personal and professional life;

- A means of empowering people with new knowledge and skills to help resolve common issues that challenge global society's collective life now and in the future;
- A holistic approach to achieve economic and social justice and respect for all life;
- A means to improve the quality of basic education, to reorient existing educational programmes and to raise awareness.

According to Wade (2008), the EfS examines sustainability at different levels from the personal and psychological to the organizational, local, national and global levels from a value perspective with the goal of sustainable change. It focuses on sustainable planning, alternative energy, land education, human rights education, conflict resolution, futures education, anti-racism, and intercultural education. The core concept of EfS is the agency of human being, this concept can be very useful in building an ethical framework for action (Dower 2003). The EfS process is based on a systemic approach that emphasizes contexts to create overall images of phenomena. Thus, it provides "a holistic approach by recognizing the complex, interrelated nature of all aspects of the world around us from the individual to the global level" (Sterling 2005, p. 23). The EfS is a lifelong process in which much of our learning takes place outside the formal sector. Wade (2008) believes that the EfS can provide a framework based on the idea of multidisciplinary to bring together related fields.

Some progressive steps have been taken through sustainability education, ESD and EfS. However, attitudes, values, and behaviors have not sufficiently adjusted to the much-needed sustainable lifestyles. Therefore, Sterling (2008, p. 64) argues that we need for anticipative education to help identify new conditions and discontinuities faced by current generations, e.g., the massive challenges of global warming, species extinction, economic vulnerability, social fragmentation and migration, endemic poverty, the end of cheap energy, and more positively, the rise of localism, participative democracy, green

purchasing, ethical business, and efforts to achieve a low carbon economy. Consequently, Sterling provides the concept of SE as a basis for education, emphasizing the nature, policy, and practice of educational thinking as a whole.

Sustainable Education for Sustainable Transformation

According to Sterling (2008), the concept of "sustainable education" refers to a change in culture in the way education and learning are understood. SE has been considered as renewable resources to be geared toward the acquisition of key competences of the twenty-first century including sustainable lifestyles, work, and habitat (Branden 2015). The heart of it lays on an ecological orientation. Other terms describing the nature of the SE are "holistic," "systemic," and "inclusive" showing that SE is relative, committed, ethically oriented, and globally and locally relevant. SE signifies a systemic change in educational thinking and practice that arises around the poles of holism, systemic thinking, sustainability, and complexity. SE enables education that is appropriate, takes into account and responds immediately to changes in circumstances, and supports the development of students' adaptability, creativity, self-reliance, hope, and resilience. SE combines education and learning theories integrating the best aspects of liberal education with new ideas of transformative education, capacity building, creativity, and adaptive management which are considered as a part of the new SD program at all educational level (Sterling 2008).

SE requires education policies and practices that are sustaining, tenable, healthy, and durable (Sterling 2008, p. 65):

- Sustaining: it helps sustain people, communities, and ecosystems;
- Tenable: it is ethically defensible, working with integrity, justice, respect, and inclusiveness;
- Healthy: it is itself a viable system, embodying and nurturing healthy relationships and emergence at different system levels;

- Durable: it works well enough in practice to be able to keep doing it.

Traditional teaching cannot bring about a change in the whole system, but everything continues in a more or less the same way (so-called first-order change). Achieving change requires at least “a second-order change” that involves re-examining assumptions through systemic and in-depth learning toward broader awareness at the personal, organizational, and community levels.

Thus, an ecological orientation means seeking synergies between all aspects of education: ethos, curriculum, pedagogy, leadership, use of resources, architecture, and community connections (Sterling 2008).

The purpose of SE is to promote equity, improve the quality of life and well-being, conserve natural resources, and protect health (Jämsä 2006, p. 28). Jämsä emphasizes that the principles of SE are similar to the general principles of education and that SE is an essential as part of ethical education. He also believes that SE can awaken people to a deep personal awareness of the various consequences of moral choices. According to Alcalá and Gutiérrez (2019), SE should include innovative pedagogy that supports students’ understanding of social reality. In teaching and learning, crucial issues are values (e.g., respect, trust, participation, community, justice, participatory democracy, openness, and critical reflection). The educational process should be planned and implemented from a holistic perspective (Burns 2011), and SE practice extended to be systemic and cross-disciplinary (Stevenson et al. 2017). At SE, the core of education is a critically important “learning about learning” process that directly affects the opportunities for a more sustainable future for all.

Despite the distinctions that can sometimes be drawn between sustainability education, ESD, EfS, and SE, they all share a vision of quality education and a society that lives in balance with earth’s carrying capacity (cf. Sterling 2010). According to Sterling (2004a), a key question concerns “response-ability,” that is, how different sectors are able to respond to the wider context of the unsustainability crisis and the opportunities of

sustainability. This is a difficult challenge that requires learning from all those involved in educational planning, policy, and practice. Sustainability requires the development of systematic and integrative activities as well as systemic thinking in education (Sterling 2004b). Ultimately, the sustainability transition requires a shift of culture from a mechanistic and reductionist toward a more ecological and holistic one. Achieving these changes requires designing education systems from a sustainability perspective.

Teachers’ Competencies of Sustainability and SE

The key skills for SD are systems thinking competency, anticipatory competency, normative competency, strategic competency, collaboration competency, critical thinking competency, self-awareness competency, and integrated problem-solving competency (UNESCO 2017). Systems thinking competency means the abilities to recognize and understand relationships, to analyze complex systems, to think of how systems are embedded within different domains and different scales and to deal with uncertainty. Anticipatory competency comprises the abilities to understand and evaluate possible, probable, and desirable futures, to create one’s own visions for the future, to apply the precautionary principle, to assess the consequences of actions, and to deal with risks and changes. Normative competency includes the abilities to understand and reflect on the norms and values that underlie one’s actions and to negotiate sustainability values, principles, goals, and targets in a context of conflicts of interest and trade-offs, uncertain knowledge, and contradictions (UNESCO 2017).

Strategic competency is the ability to collectively develop and implement innovative actions that further sustainability at the local level and further afield. Collaboration competency includes the abilities to learn from others, to understand and respect the needs, perspectives, and actions of others, to understand, relate to and be sensitive to others, to deal with conflicts in a group, and to facilitate collaborative and participatory problem-

solving. Critical thinking competency comprises the ability to question norms, practices, and opinions; to reflect on one's values, perceptions, and actions, and to take a position in the sustainability discourse. Self-awareness competency is the ability to reflect on one's own role in the local/global community and society, to continually evaluate and further motivate one's actions, and to deal with one's feelings and desires. Integrated problem-solving competency is the overarching ability to apply different problem-solving frameworks to complex sustainability problems and develop viable, inclusive and equitable solution options that promote SD, integrating the abovementioned competences (UNESCO 2017).

The key competencies for sustainability can be understood as transversal, multifunctional, and context independent (Rychen and Salganik 2003). They represent what citizens who work to achieve sustainability will particularly need to deal with today and the future's complex challenges. They are relevant to all SDGs and enable individuals to relate the different SDGs to each other – to see “the big picture” of the 2030 Agenda for Sustainable Development (United Nations 2015). The key competencies represent cross-cutting competencies that are necessary for all learners of all ages worldwide. Thus, teachers should be able to master the issues concerning the key competences for sustainability and be able to apply their knowledge in teaching situations.

According to Brundiers and Wiek (2017), the knowledge dimensions required for integrative SD include content knowledge, methodological skills, communication skills, collaborative teamwork, participant engagement, project leadership ability, continuous learning ability, and self-care. By fostering competencies of SD (Lozano et al. 2017; Rieckmann 2019), it is important to steer education in a global direction to achieve social justice for present and future generations while respecting cultural diversity. At the local level, teaching should be favored a variety of formal, non-formal, and informal learning to accelerate the implementation of sustainable solutions (Lockhart 2016).

SE is a lifelong learning and an integral part of a quality, comprehensive, and transformative education concerning content, environment, and learning outcomes, as well as pedagogy (Ghemawat 2017). Beside environmental issues, interaction between society and the environment is in the core of teaching, studying, and learning processes. Cooperation between fields of education should be encouraged, especially in matters of environmental protection, human rights, social and economic development. The values, knowledge, and skills needed for sustainable environmental management, the promotion of social justice, and the eradication of poverty are key to education (Coriddi 2008). SE can be seen as an instrument of empowerment that inspires individuals and society to adopt sustainable lifestyles for the benefit of present and future generations.

Summary

The issues of sustainability and SD have received more national and international attention in recent decades. Numerous concepts are used interchangeably in education of sustainability. The following terms are most commonly used: “sustainability Education,” “education for sustainable development (ESD),” “education for sustainability (EfS),” and “sustainable education (SE).” Although they contain similar ideas, their starting points, goals, and approaches differ somewhat.

Over the years, sustainability education has expanded from an original ecological perspective to include social, ethical, and transformative aspects as well. Also ESD and EfS aim to find sustainable solutions to local and global problems through a transformative perspective. The core ideas of ESD are social justice and cultural diversity while EfS emphasizes the agency of human being in order to achieve sustainable change from a value perspective. Like early sustainability education, also SE is based on ecological orientation. Ecological orientation means that the sustainable use of natural resources must also be taken into account when promoting justice and improving the quality of life and well-being. SE should

support students' understanding of social reality. Teaching and learning of SE should be based on values and in the holistic, systemic, and cross-disciplinary planning and implementation processes.

Today, the crucial goal is to learn to live sustainably. This requires education systems, educational institutions, and educators with a willingness to tackle sustainability problems and the ability to respond to them.

concern for any country seeking to create its economy. Historical information shows that the connection between mankind and natural resources was solely extractive. In the 1980s, the United Nations (UN) established the World Commission on Environment and Development (UNCED), also known as the Brundtland Commission, in view of the issues produced by this exploration. Brundtland Commission report (1987) became a framework for sustainable energy development (Jefferson 2005). The Commission highlighted the danger of overuse of natural resources without taking into account ecosystem ability, highlighting the incompatibility between sustainable development and the current manufacturing and consumption trends (Camio et al. 2018).

Energy requirements have been steadily growing to sustain countries' development. At the same moment, atmospheric levels of greenhouse gases (GHGs) are growing, especially carbon dioxide (CO₂), intensifying the natural greenhouse effect and the heat it produces. The rise in energy consumption has developed severe issues in this context. The present patterns of global energy production and consumption are based on fossil fuels, resulting in local pollutant and GHG emissions and endangering the planet's long-term supply as a nonrenewable source.

Sustainable Energy

Sefer Aydoğan

Military and Social Science Department, Air Force Academy/National Defense University, Istanbul, Turkey

Synonyms

Biofuels; Biomass; Energy efficiency; Energy engineering; Hydrogen; Renewable energy; Sustainable development

Definition

Increasing energy consumption in the modern world is a severe issue. Policies aimed at ensuring energy efficiency have therefore become a

Introduction

There is pressure on the world's main economies to enhance their energy efficiency, and people need to discover methods to decrease energy requirements and prevent energy waste and pollution in order to achieve sustainable development. Also essential is the long-term link between energy consumption and the real GDP of 25 countries of the Organization for Economic Cooperation and Development (OECD) (Camio et al. 2018).

Belke et al. (2011) show a direct link between energy consumption and economic development. Consequently, when planning efficient energy conservation interventions, it is vital for policymakers to consider the direct effect of energy consumption on economic growth. Not only do unsustainable energy production and consumption habits threaten human health and

quality of life, but they also have a profound impact on ecosystems and contribute to climate change. However, sustainable energy not only addresses these problems head-on, but is also an engine for poverty reduction, social progress, equity, increased resilience, economic growth, and environmental sustainability.

Policy Suggestions

The future of sustainable energy relies on a higher share of renewable energy, particularly in developing nations. Considering that there are greater levels of energy use and environmental effects from this use with greater rates of financial activity, energy efficiency can provide extra safety and advantages, such as decreased CO₂ emissions and decreased energy imports. These advantages complement each other, resulting in a decrease in the energy needed per unit of economic product, improving the effectiveness of the economy and ensuring that output can be accomplished with less energy and thus less use of natural resources and less harm to the environment.

UNDP's work on energy is in line with SDG 7's primary energy objectives: ensuring universal access to affordable, reliable, and modern energy services; working with nations to create energy systems and use them more effectively; and working to boost the worldwide share of renewable energy. The work of UNDP also involves a focus on sustainable cities and transport projects, with a focus on more integrated alternatives for electricity, mobility, land use, and waste management. Through these efforts, countries are able to make progress against each and every one of the SDGs, while contributing to global climate action (UNDP 2019).

As part of the 10-year UN Framework Program on Sustainable Consumption and Production, the EU has created sustainable consumption and manufacturing policies. In this context, as the significance of energy input, the research of energy consumption and manufacturing trends could be particularly important (Garccia-Alvarez

and Soarez 2018). The EU requires the below-mentioned policy suggestions:

- Renewable energy targets
- An improvement of coordination of economic units
- The elimination of administrative barriers to renewable energy consumption
- An acceleration of renewable heating technologies
- Financing renewable energy projects
- Identification of priority sectors
- Energy labeling and ecodesign directives
- Developing energy technologies (European Commission 2014)

It is therefore essential to continue investing in regulatory measures that enable more sustainable energy to be produced, distributed, and used. To be able to live within ecological boundaries, they should be implemented at all levels of culture (consumers, manufacturers, and local authorities) (Garccia-Alvarez and Soarez 2018).

UNECE's work on sustainable energy aims at improving access for all to affordable and clean energy and helping to decrease greenhouse gas emissions and the energy sector's carbon footprint in the region. It fosters dialog and collaboration between governments, energy industries, and other stakeholders on global policy (UNECE 2019). The focus is on energy efficiency, cleaner fossil-fuel electricity generation, renewable power, methane coal mine, natural gas, energy and mineral reserves and resources classification, and energy security (UNECE 2019).

From the point of perspective of sustainable energy development, renewables are widely available, ensuring greater security of power supply and reducing dependence on oil imports from politically volatile fields. In terms of both local emissions (such as particulate matter, coal, and lead) and greenhouse gases (coal dioxide and methane), renewables are less polluting and cause global warming. They also require more labor-intensive workers per energy unit than standard fossil fuels. Although technologically mature, some renewable energy sources are more costly than fossil-fuel-generated energy. This is

especially the case with the “fresh renewables.” Traditional biomass is often not the object of business operations, and it is hard to assess its expenses, except for economic ones. Despite its attractiveness from a sustainability view, cost remains the basic obstacle to the widespread implementation of traditional biomass (Goldemberg 2007).

Thus, it is worth evaluating and estimating the potential of countries’ energy-saving and emission cuts as an attempt to progress toward building a world economy that is effective in resource utilization. Such an assessment can provide helpful data for energy and environmental policies as well as contribute to the sustainability of nations with major financial impact in the globe (Camiato et al. 2018).

Summary

The sustainable energy is referred to energy that meets the needs of the present society without affecting the ability of future generations to meet their needs. Sustainable energy is a result of the earth’s natural resources which implies it is replenished constantly via natural resources. Hence, it is inexhaustible. Several forms of energy can be considered sustainable, such as widely known wind, solar, and water and also bioenergy and geothermal energy, biological energy (straw, manure, and other agricultural byproducts), geothermal energy like geysers.

Description

The energy systems, producing electricity and heating/cooling for buildings, should operate carbon neutrally by 2050, in order to limit the global warming to 1.5 °C above preindustrial levels. This requires significant changes in the energy systems and market structures, as the current systems are mainly based on the use of fossil fuels. The Intergovernmental Panel on Climate Change (IPCC 2018) names energy demand reductions, decarbonization of electricity and other fuels, and electrification of energy end use, among others, as pathways to limiting the global warming.

Introducing energy systems running on totally renewable energy sources is a challenge that involves large number of different players with different roles in building the future energy systems and markets. The roles of energy system players are changing: building users, formerly in energy terms consumers or customers, become prosumers. The structures of energy networks are also changing, new production technologies of electricity and heating energy are entering the markets. This is leading to more decentralized and versatile production structures.

The future integrated energy systems are, compared to the current ones, much more dynamic and versatile. Energy production will be more decentralized, and more technologies are utilized in energy production, consumption, and storing. Future energy networks operate on two directions, this makes it possible basically for anyone to be able to also produce and sell excess energy to the market, when it is profitable.

Introduction and Background

The energy systems, producing electricity and heating/cooling for buildings, should operate carbon neutrally by 2050, in order to limit the global warming to 1.5 °C above preindustrial levels. This requires significant changes in the energy systems and market structures, as the current systems are mainly based on the use of fossil fuels. The Intergovernmental Panel on Climate Change

(IPCC 2018) names energy demand reductions, decarbonization of electricity and other fuels, and electrification of energy end use, among others, as pathways to limiting the global warming.

Buildings have an important role in reaching the environmental targets, as the buildings and building construction sectors are responsible for nearly 40% of global final energy consumption and nearly 40% of total direct and indirect CO₂ emissions. In 2017, buildings and appliances were responsible for around 30% of global final energy use. Building energy use increase was 0.8% in 2016 and 20% between 2000 and 2017. This growth was primarily driven by increases in floor area, occupancy, and access to services along with increases in activity, including changes in population, climate, and the use of appliances (IEA 2018a).

Some major increases in energy consumption have taken place since 2000. Energy consumption from space heating has nearly doubled, energy intensity per floor area in the residential sector has increased by over 80%, and energy consumption by appliances has grown by 58%. However, at the same time, Space heating, water heating, lighting, and cooking have also experienced improvements of more than 20% in energy intensity per floor area (IEA 2018a).

The International Energy Agency (2018a) highlights the potential for global building energy demand to remain flat between now and 2040, despite total building floor area growing by 60%. There is a large energy efficiency potential in buildings; according to IEA's estimate, by 2040 buildings could be 40% more energy efficient than today. Greatest energy savings are estimated to come from space heating – over a quarter of the savings potential. Water heating efficiency could improve by 43%, and space cooling efficiency could be improved by doubled air conditioner efficiency.

Along with decarbonization, the share of electricity in total energy consumption is expected to increase. Future renewable energy technologies mainly produce electricity (photovoltaic solar panels, wind power, hydro power, wave power, . . .), which is then used also for heating purposes, by utilizing, for example, heat pump technology.

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 1 Regional energy collaboration context. (Adapted from Mikkola et al. (2015))

In colder climates, heating of spaces still remains an important part of the energy consumption palette, and district heating is expected to have a role also in the future integrated energy systems. IEA has stated in 2018: “For space heating, if all countries were to achieve best practice market averages (such as in Japan and Scandinavia), global heating energy consumption could be cut in half” (IEA 2018a).

Managing energy production, under different seasonal weather and climate conditions, raises many challenges for the energy markets under transition to decarbonized operation.

Energy Grid Players

Regionally, planning energy management involves long-term planning of energy sources management, suitable production technologies, and planning of distribution grids, based on forecasted energy demand. In order to reach and maintain a feasible balance in energy production, supply, and demand, with affordable overall costs, different players should be involved in the

planning and development of the regional energy system (Fig. 1).

In energy systems, the efficiency is not the only important criterion, but balancing between the elements of the overall system also has an important role. Close collaboration between all partners producing, consuming, or transmitting energy is required to optimize the system (Jussila et al. 2014).

In the regional context, both heat (and/or cooling) and electricity grids are often available, at least in the areas where space heating is required during cold periods. The interconnections of electricity and thermal energy systems are presented in Fig. 2.

Heating and electricity grids are different by their nature: heating grids are local, due to the heat losses in the distribution grid (in average 8–9% in Finland). Electricity can be transported with lower energy losses (in Finland, approx 3%) than heat. Local electricity grids are usually connected to a national grid, which can then further be connected to a neighbor country’s national grid. Such is the case in Nord Pool market area, which includes Finland, Sweden, Norway, Denmark, Estonia,

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 2 Interconnections of electricity and thermal energy in integrated energy systems. (Adapted from IEA (2014))

Latvia, and Lithuania. Thus, for a customer, there is a large selection of electric energy sources, with various prices, and large market area ensures that demand is met by the lowest cost electricity generation. On the contrary, in the local heating grid the customer is bound to the fuel selection available in the local production plants.

Electricity and heat grids and markets integrate in Combined Heat and Power production (CHP), and when heat storages are added to the system. This enables the optimization of heating energy acquisition costs, as electricity can be transformed into heat energy by utilizing heat pumps, and then stored to be used at appropriate time in the district heating network. During periods of cheap electricity prices (excess renewable production), this option can be very profitable.

Planning the regional energy system involves planning of energy production structure in the area. The decision makers have to take a stand on how self-sufficient the region should be in energy production and sources. If there are

renewable energy sources available inside the region, utilizing them would likely benefit the region by creating business opportunities and jobs. Between countries, changes in policies could result in short- or long-term problems in electricity export or import. To avoid such partial optimized country-specific policies, EU is building Energy Union to ensure secure, sustainable, competitive, and affordable energy for its citizens (European Commission 2015).

Electricity Grid Players

In traditional electricity systems, electricity is produced in generation plants and then distributed to customers via the main grid (e.g., 110–400 kV), high voltage distribution networks (110 kV), and distribution networks (20, 10, 1, or 0.4 kV). Currently, it is possible also for the consumers to produce electricity and sell it to the grid, depending on the market. This has not only

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 3 Overview of the electricity system showing both technical and economic subsystems; the black line indicates the route of

physical electricity; the yellow line shows the money flow (excluding network tariffs) (Adapted from Baumgartner 2014)

given rise to new business opportunities, but also challenges, as the electricity customers can now buy and sell energy.

The main actors in a modern electricity market are shown in Fig. 3, the Nordic electricity market is used as an example. Transmission system operator (TSO) operates the main (national) grid and is responsible for maintaining system balance in national level. The final customers, apart from the large industrial ones, buy their electricity from the retailer of their choice, which again, is buying electricity from producers in wholesale electricity markets, in which also large industrial consumers operate. Open competition has been introduced to wholesale and retail electricity markets. DSO (Distribution System Operator) charges for the electricity distribution, which means that the customer gets two bills; one concerning the energy consumption and one concerning the distribution. DSO, similar as TSO, runs a natural monopoly, since there is only one local distribution grid for electricity, and it would not be a cost-efficient solution to build parallel competing networks. Hence, the distribution bill cannot be invited to tender. On

the other hand, DSO is regulated by the authority to avoid the misuse of the monopoly position.

Residential consumer's electricity bill consists typically of distribution fee, energy fee, and taxes. In Finland, electricity tax and value-added tax form approximately one third of the average consumer's electricity bill. One third of the total costs is transport cost related, and one third comes from the energy sales.

Heating Grid Players

District heating (DH) is common in the areas having high space heating demand, due to its ability to provide reliable heating energy with high system efficiency. When utilizing Combined Heat and Power (CHP) technology, also power (electricity) is produced, in addition to heat. This improves the overall efficiency of energy production.

Traditionally, a DH system consisted of three main system components: production, distribution, and consumption. The thermal energy produced at the production plants is transmitted to

customers as hot water in a closed district heating network, consisting of two pipelines (supply and return pipes). Customers get their heat energy from the DH supply stream through heat exchangers, the return pipe conveys cooled water back to the production plant, to be heated again. DH water does not circulate in the building heating network (Finnish Energy 2019). “The four generations” of DH are presented in Table 1.

The player chart of DH system is similar to the electricity system (Fig. 4). The traditional customer–retailer relationship has also been similar to electricity systems: customer consumes, retailer delivers. Currently, also DH networks can be opened for new energy producers and retailers.

The heat energy demand of buildings is determined in the customer end of the chain, consisting mainly of heat losses via building envelope, heating demand for ventilation/air conditioning purposes, and heating demand of hot domestic water. Distribution losses and losses at the production site determine the total primary energy demand, along with the customer energy demand (Fig. 5). The primary energy demand of the chain is the total amount of energy needed to compensate the consumption and losses; hence the emissions related to the energy consumption at the customer end include also the emissions caused by the distribution and production losses. The analogy is the same when the environmental impacts of electricity consumption are under consideration. The main difference between these energy systems are losses: electricity can be transmitted much longer distances with relatively small energy losses.

Prosumer in an Integrated Energy System

The prosumers of an energy system are customers who can both consume and produce energy to the grid. Produced energy (electricity or heat) can be used to satisfy customer’s own demand, or sold to the distribution grid. The most common

application of being a residential prosumer is producing electricity with a photovoltaic production unit. Depending on the design of the solar plant, and the structure of local electricity market, all produced electricity may be consumed by the customer, or excess energy can be sold to the grid. In principal, a customer can be a prosumer also in regional heating energy system (DH, or a smaller local heating grid). However, not so many DH networks are yet open for two-way connections, apart from some industrial cases.

The importance of the prosumer’s role is likely to increase significantly in the next decades, as the pursuit of reaching the carbon neutrality will lead to restricting of peak loads by financial incentives and other policy measures. Different demand response (DR) programs are being introduced to support the development leading to more energy efficient and renewable energy-based energy system.

The collective term Demand-side integration (DSI, Fig. 6) includes the programs aimed at integrating the demand (customer) side into energy system operations. Utilizing DSI allows electricity systems to accommodate higher shares of renewables, increase system efficiency, and reduced costs (IEA 2018b).

DSI can be implemented through tariff design and retail programs, where consumers can be exposed to pricing signals that allow them to adjust their consumption (Implicit DSM). Demand response, or explicit DSM, can be carried out through wholesale and load control programs. These are generally mediated by a demand aggregator, which enables consumer participation in operations in wholesale, capacity, or ancillary markets (IEA 2018b).

The DSI programs can contribute to the improving of the power markets, providing system services and shaping demand in a way that helps facilitate variable renewable energy integration. Costly investments in power plants or infrastructure can be postponed or even avoided, fuel cost savings can be gained, and critical power outages can be avoided (IEA 2018b).

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Table 1 The four generations of DH. (Adapted from Lund et al. (2014))

	1st Gen. DH	2nd Gen. DH	3rd Gen. DH	4th Gen. DH
Period of best available technology	1880–1930	1930–1980	1980–2020	2020–2050
Distribution and demand				
Heat carrier	Steam	Pressurized hot water mostly $T_{\text{supply}} > 100\text{ }^{\circ}\text{C}$	Pressurized hot water, mostly $T_{\text{supply}} < 100\text{ }^{\circ}\text{C}$	Low-temperature water, $T_{\text{supply}} = 30\text{--}70\text{ }^{\circ}\text{C}$
Pipes	In situ insulated steel pipes	In situ insulated steel pipes	Pre-insulated steel pipes	Pre-insulated flexible (possibly twin) pipes
Circulation systems	Steam pressure	Central pumps	Central pumps	Central and decentralized pumps
Substations heat exchanger	No	Tube-and-shell heat exchangers	Without or with plate heat exchangers	Probably mostly with plate heat exchangers Introduction of flat-stations (decentralized supply of hot water in new buildings)
Buildings	Apartment and service sector buildings in the city	Apartment and service sector buildings $200\text{--}300\text{ kWh/m}^2$	Apartment and service sector buildings (and some single-family houses) $100\text{--}200\text{ kWh/m}^2$	New buildings: $<25\text{ kWh/m}^2$ Existing buildings: $50\text{--}150\text{ kWh/m}^2$
Metering	Condensate meters in order to measure the amount of steam used	Initially only flow meters in substations, later replaced by heat meters. Annual or monthly readings Sometimes use of allocation meters on radiators for internal distribution of heat costs	Heat meters and sometimes additional metering of flow in order to compensate for high return temperatures Wireless readings introduced for more frequent readings	As earlier but continuous reading used for continuous commissioning of customer heating system
Radiators	High-temperature radiators ($90\text{ }^{\circ}\text{C}$) using steam or water	High-temperature radiator ($90\text{ }^{\circ}\text{C}$) using district heating water directly or indirectly	Medium-temperature radiators ($70\text{ }^{\circ}\text{C}$) using district heating water directly or indirectly Floor heating	Floor heating Low-temperature radiators ($50\text{ }^{\circ}\text{C}$). Indirect system
Hot water	Hot water tanks heated directly with steam or from a secondary water circuit	DHW tank heated to $60\text{ }^{\circ}\text{C}$ Circulation at $55\text{ }^{\circ}\text{C}$ when needed	Heat exchanger heating DHW to $50\text{ }^{\circ}\text{C}$. Domestic hot tank heated to $60\text{ }^{\circ}\text{C}$. Circulation at $55\text{ }^{\circ}\text{C}$ when needed	Very efficient local heat exchanger heating DHW to $50\text{--}40\text{ }^{\circ}\text{C}$ In district heating systems with supply temperature of $30\text{ }^{\circ}\text{C}$, a heat exchanger preheats DHW and a heat pump with buffer tank and heat exchanger increases DHW temperature to $40\text{ }^{\circ}\text{C}$ by cooling down the return temperature

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 4 Stakeholders of DHC (District Heating and Cooling) (Adapted from Euroheat & Power 2012)

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 5 Primary energy consumption in a regional heating system (Adapted from Vinokurov and Luoranen 2015)

**Managing the Overall System:
Cooperation Between Prosumers,
Producers, and Operators**

Managing the future integrated energy system involves many different actors. Heating and

electricity grids are integrated through energy in building energy systems and energy storages, as storages are becoming more and more important part of the energy markets: Heat storages can be charged by utilizing heat pumps, when electricity price is low. The storages can

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Fig. 6 Demand side management and demand response. (Adapted from IEA (2018b))

then be discharged during the expensive electricity periods.

Electrification is a current global trend; at the moment the increase in electricity consumption caused by increasing access to electricity and electrical appliances exceeds those energy savings gained by more energy efficient building systems. This means the households' total energy, especially electricity, consumption is continuously increasing. The target of reaching the decarbonization in building-related energy consumption seems to be solved only by totally renewable electricity, i.e., mainly solar, wind, or hydropower. In addition to that, controlling the peak loads is becoming a crucial point when energy systems' efficiency and economy are considered.

In the near future, charging of large number of electric cars requires electricity systems to be flexible. On the other hand, the car batteries can also operate as storages, when connected to the grid. Furthermore, utilizing Internet of Things (IoT) technologies in home appliances will contribute to the complexity of the task of optimizing energy systems. The overall system management should keep all the players happy – end-users, prosumers, operators, and producers.

Future energy systems need to be more and more flexible, since the amount of intermittent

generation is increasing drastically, and the customer demand patterns are changing. All energy market players have important roles in this development. In Table 2, elements of power system development are described. The same analogy can be applied on heating networks.

There are several challenges to be solved, in order to accomplish the target of carbon neutral and affordable integrated energy system. IEA (2014) has published a list of barriers preventing the selection of cogeneration and efficient district heating and cooling (DHC) technologies:

- Energy efficiency is not rewarded due to market conditions and energy prices.
- Energy policies fail to reward utilization of industrial waste heat or natural cooling, in comparison to renewable energy sources.
- Nontransparent, inconsistent interconnection procedures and back-up charges.
- Lack of knowledge about co-operation benefits and savings.
- Lack of integrated heating/cooling supply planning.

Furthermore, barriers reducing economic feasibility of cogeneration and DHC include (IEA 2014):

Sustainable Energy Grids: Cooperation Between Prosumers, Producers, and Operators, Table 2 Layers of power system

Who	How	What
Institutions and actors	Policy, market, and regulatory frameworks	Hardware and infrastructure
Typical decision makers	Categories of interventions	Asset types
Energy ministry	Energy strategies Legal frameworks Policies and programs	Power plants Electricity networks Energy storages
Regulatory agency	Regulatory frameworks and decisions Power sector planning exercises Retail electricity planning	Distributed energy resources
System operator, electric utility, standards body	Power market rules and codes System operation protocols Connection codes	

Adapted from IEA (2019)

- Higher upfront investments, compared to conventional generation and distribution systems.
- Difficulties in securing fair values prices for electricity from cogeneration to the grid.
- Uncertain energy policies, lacking long-term visibility.

In addition, barriers reducing flexibility of the business structure of complex energy systems include (IEA 2014):

- Lack of energy efficiency policy coordination on supply, distribution, and end use.
- Lack of business models rewarding energy flexibility and sustainability.

Summary

The energy systems, producing electricity and heating/cooling for buildings, should operate carbon neutrally by 2050, in order to limit the global warming to 1.5 °C above preindustrial levels. This requires significant changes in the energy systems and market structures, as the current systems are mainly based on the use of fossil fuels. The Inter-governmental Panel on Climate Change (IPCC 2018) names energy demand reductions, decarbonization of electricity and other fuels, and electrification of energy end use, among others, as pathways to limiting the global warming. Regionally, planning energy management involves long-term planning of energy

sources management, suitable production technologies, and planning of distribution grids, based on forecasted energy demand. In order to reach and maintain a feasible balance in energy production, supply, and demand, with affordable overall costs, different players should be involved in the planning and development of the regional energy system.

Managing energy production, under different seasonal weather and climate conditions, raises many challenges for the energy markets under transition to decarbonized operation. Increasing cooperation between all energy field players is required, in addition to intensive research and development of technologies, market structures, and business models, to achieve the ambitious targets set for mitigation of global warming. Since the demand for energy, due to seasonal and periodical changes in temperatures and weather conditions, is not constant locally or nationally, storages for heat and electricity are required for shorter (milliseconds to hours to days) and longer (months, seasons) periods. In addition, DSI programs are needed to maximize the energy efficiency of the energy systems, and to minimize the overall costs.

Sustainable Entrepreneurship

Ayça Kubra Hizarci-Payne
Faculty of Business, Dokuz Eylul University,
Izmir, Turkey

Synonyms

Environmental, eco, green, and social entrepreneurship

Definition

Business practices led the emergence of numerous environmental and social problems, which constitute the major source of sustainability issues. Environmental degradation and social problems have sparked the attention of scholars and practitioners to find solutions for these problems. In contrast to conventional entrepreneurship in which the core goal is economic gains, sustainable entrepreneurship has gained an aspirational appeal in motivation to seek substantial solutions for environmental and social problems. As a new conceptualization of entrepreneurial activities, sustainable entrepreneurship reflects the entrepreneurial efforts for exploring, developing, and exploiting opportunities to promote sustainable development through environmental and social gains. In this domain, entrepreneurs who start a venture to serve for societies' interest by tackling the facets of social and environmental issues are usually referred to as sustainable entrepreneurs. Although there are ambiguities about the conceptualization of sustainable entrepreneurship, the definition that reached to the consensus reflects the consistency of sustainable development goals with entrepreneurial activities. In line with this, Young and Tilley (2006) view sustainable

entrepreneurs as “the individuals who holistically integrate the goals of economic, social and environmental entrepreneurship into an organization that is sustainable in its goal and sustainable in its form of wealth generation” (Tilley and Young 2009, p. 88). Accordingly, sustainable entrepreneurship is defined as exploration, creation, and exploitation of opportunities with economic, social, and environmental gains. In conjunction with this definition, sustainable entrepreneurs pursue profitable solutions for sustainability issues including social and environmental goals through offering more innovative and sustainable alternatives.

Introduction

The severe global climate crisis, increasing depletion of natural resources, and social inequality mirror the reality that the world is not consistent with sustainable development. The accelerating sustainability challenges show that existing solutions are not adequate to keep natural and social capital at a critical level. Therefore, the concept of sustainable entrepreneurship as a nascent research stream has received burgeoning interest from scholars (Binder and Belz 2014; Thompson et al. 2011). Entrepreneurs are considered as the key change engines that ignite the transformation worldwide (Belz 2013; Hall et al. 2010). In contradistinction to the traditional or conventional view of entrepreneurship which solely focuses on economic development (e.g., Kirzner 1973; Schumpeter 1942), sustainable entrepreneurship underlines the balance in the triple bottom line of social, environmental, and economic aspects in the aim of creating a more sustainable environment (Cohen et al. 2008; Cohen and Winn 2007; Thompson et al. 2011). The concept of triple bottom line was pointed out by Elkington (1997) who asserted that firms should go beyond their financial gains and focus on social and environmental aspects of their business interactively (Slaper and Hall 2011). Accordingly, triple bottom line is viewed as a performance measurement that observes the balance between economic, environmental, and social gains in which the

main focal points are “people, planet, and profit” (Bell and Stellingwerf 2012). In this respect, sustainable entrepreneurs are those who conduce the business practices that simultaneously integrate those dimensions without ignoring social and environmental aspects. In this sense, there is a growing attention in the roles of entrepreneurs regarding social, environmental, and economic aspects of sustainable development (Binder and Belz 2014; Schaltegger and Wagner 2011; Schaltegger et al. 2016).

Sustainable entrepreneurship is associated also with sustainable development that refers to “the needs of the present without comprising the ability of future generations to meet their own needs” (Brundtland Commission 1987) as it provides an integrated perspective of sustainable development and entrepreneurship. Sustainable development that has risen as an influential as much as controversial topic for business and policy makers delivers the awareness that a fundamental transformation is urgent to extenuate the hazardous environmental and societal effects of existing unsustainable business practices (Hockerts and Wüstenhagen 2010). In addition, sustainable development is addressing the core notion that all resources are scarce which requires people to live in those limits. This interplay between sustainable development and entrepreneurship led new conceptualizations of entrepreneurship including green, ecopreneur or environmental entrepreneur, social entrepreneur, and sustainable entrepreneur (Muñoz and Cohen 2018; Schaltegger and Wagner 2011; Zahra et al. 2009). While the green, ecopreneurs, or environmental entrepreneurs pursue an environmental perspective, social entrepreneurs associate their business activities to the accomplishment of societal development. Accordingly, sustainable entrepreneurship has its origins from environmental and social entrepreneurship field, and it encompasses creation of sustainable ventures where the social and environmental issues are viewed as the ultimate goal (Muñoz and Dimov 2015; O’Neill et al. 2009). Sustainable entrepreneurs address economic, social, and environmental gains interactively and simultaneously, while social or environmental entrepreneurs focus on one or two

dimensions (Binder and Belz 2014). The common feature that combines those entrepreneurs under the same umbrella is the avoidance of only profit maximization and ignoring the environmental and social gains. Despite the overlap of the conceptualization of sustainable entrepreneurs and social and environmental entrepreneurs, the simultaneous triple focal view differentiates sustainable entrepreneurship from social and environmental entrepreneurs (Belz and Binder 2017; Thompson et al. 2011). Shepherd and Patzelt (2011, p. 137) define this multiple goal implementation as “the preservation of nature, life support, and community in the pursuit of perceived opportunities to bring into existence future products, processes, and services for gain, where gain is broadly construed to include economic and non-economic gains to individuals, the economy, and society.” In this vein, sustainable entrepreneurs who are the sources of sustainable ventures that promote environmental protection and solution for social problems are motivated by advancing sustainable development (Hall et al. 2010, Shepherd and Patzelt 2011). Accordingly, sustainable entrepreneurship is an overarching view of entrepreneurial efforts covering social, environmental, and economic developments. Briefly stated, sustainable entrepreneurship highlights the exploration and exploitation of opportunities to produce goods and services that are in line with sustainable development goals (Pacheco et al. 2010; Shepherd and Patzelt 2011). Sustainable entrepreneurs are resonated with efforts for promoting environmental protection, stopping environmental degradation, achieving energy efficiency, increasing social equality and education, reducing poverty and unemployment, and solving social problems through sustainable innovations regarding products, services, and processes. More broadly, these socially and environmentally conscious agents are motivated and dedicated to promoting sustainable development worldwide through their environmentally and socially innovative efforts. Thus, sustainable entrepreneurs are considered as the nexus between sustainable development and innovation. Sustainability innovation and sustainable entrepreneurship are considered as the primary drivers of sustainability that enable the integration

of economic, environmental, and social system (Cohen and Winn 2007; Parrish 2007; Young and Tilley 2006). Especially, innovations are considered as the central point for sustainable entrepreneurs (Lüdeke-Freund 2019). In essence, sustainable entrepreneurship is viewed as the realization and implementation of sustainable innovations in order to meet the unmet demands of stakeholders and provide benefits to society.

Related Issues

Entrepreneurs who pursue sustainability seek to change the existing market structure by creation of value for a nation's society, environment, and economy. Through their innovative approach, sustainable entrepreneurs are exerting substantial impact on their institutional environment including markets and societies. In order to be effective in this transformation process, sustainability-oriented business models are employed in which a triple bottom line approach is incorporated with the interests of stakeholders, environment, and society. Sustainable business models play a vital role in implementation of sustainable innovations in products, processes, and services that are considered as the drivers of competitive advantage (Bochen et al. 2014).

Being socially and environmentally aware individuals, sustainable entrepreneurs are fulfilling a crucial role in societies since they discover and provide solutions for problems that are neglected or underestimated by the governments and other related organizations (Elkington and Hartigan 2008). Despite the contributions of sustainable entrepreneurs, there are hurdles that they can face. Entrepreneurs who start their sustainable venture can experience various challenges or barriers that can hinder their growth and success of their venture. For instance, sustainable entrepreneurs can be exposed to market imperfections and governmental interventions that can favor the existing technologies and interests of the incumbents (Schaltegger and Wagner 2011). In this regard, governmental institutions can enable nurturing sustainable entrepreneurial activities (Muñoz and Cohen 2018). Policies that are

conducive to create an appropriate climate for sustainable entrepreneurs to explore, experiment, and exploit with required technologies that can provide engaging in more sustainable business models should be implemented (Silajdžić et al. 2015). Another challenge which needs to be mentioned is the uncertainty of undertaking sustainable innovations (Schaltegger and Wagner 2011). In this vein, scholars pointed out that sustainable entrepreneurs need to eliminate market imperfections and external factors by commercialization of the solutions of the society and transformation of markets through providing benefits to stakeholders (Cohen and Winn 2007; Freudenreich et al. 2019).

Future Directions

Societies are substantially facing environmental and social challenges. In this regard, sustainable business practices of entrepreneurs are aiming to deploy triple bottom line of environmental, economic, and social gains instead of addressing short-term profits (Elkington 1997). In this process, the main challenge is the integration of the three aspects of the bottom line. Integration requires comprehensively understanding and analyzing the sustainability aspects in order to overcome any possible trade-off between the three aspects and keep simultaneously the effectiveness of each aspect including social, environmental, and economic gains. Those difficulties can be overcome by sustainable business models in which sustainable development is the focal goal. Moreover, governments should engage policies that can conduce the environment where sustainable entrepreneurial actions can resolve the challenges and achieve efficiency in functioning of markets for limited environmental and social resources.

Summary

Entrepreneurs who start their ventures in motivation to create values regarding triple bottom

line factors are called as sustainable entrepreneurs. Akin to the entrepreneurship research stream which ultimately points out the economic gains, sustainable entrepreneurship embodies meeting the economic, social, and environmental needs of the societies simultaneously. Sustainable entrepreneurs are willing to take risks and overcome the challenges to achieve their sustainability-oriented goals. Therefore, sustainable entrepreneurship plays an indisputable role in the transformation of world markets by creating economic, social, and environmental values through the sustainable innovations and business models. In other words, sustainable entrepreneurs are the key agents to deal with the increasing sustainability challenges and to realize sustainable development goals. It is important to bear in mind that an institutional environment which enables the required support for the sustainable entrepreneurs is one of the crucial factors for the success of sustainability-oriented practices.

Definition

Sustainable events are managed with the aim of contributing to sustainable development through promoting inter- and intra-generational equity.

History

As the concept of sustainability became widespread, many sectors began to focus on tackling

the issues this raises. Protecting their reputation and legitimacy was obviously the main driving force for the commitment of corporations towards sustainability. While in the 1990s the concept of sustainability was already widespread among many sectors with material outputs, it was not until the beginning of the new millennium that large-scale diffusion of this concept and its associated practices occurred in service sectors. After the theme of sustainability established itself as relevant in the tourism industry (see ► [“Sustainable Tourism”](#)), starting from the end of the 1990s, and especially with the new millennium, this issue has also become of great interest for the related special event industry.

Mega-events have been pioneers in the development of sustainable event management. Particularly, the Olympic Games has served as a platform for discussion and experimentation of sustainability best practices, spreading from environmental concerns. A significant step forward was made during the Centennial Olympic Congress held in Paris in 1994, where the importance of promoting sustainable development was formally recognized and included as a value in the Olympic Charter. This led the International Olympic Committee (IOC) to the decision to create an IOC Sport and Environment Commission giving birth to a process of guideline elaboration in the field of sustainable event management. A highly influential role was also played by the 2012 London Olympics Games. Since 2005, when London won the right to host the 2012 Olympics, the Organizing Committee demonstrated high commitment to sustainability. Indeed, this event became a catalyst not only in the debate around the creation of a common framework for event sustainability but also in the development of two of the most important standards in the field: BS 8901 *Sustainability in Event Management* and ISO 20121 *Sustainable events*.

Having just over two decades of history, the theme of sustainability in event studies is still at an early stage, even if the extent of research in this field is rapidly growing, in parallel with the interests of practitioners and policy makers.

The Impact of Events from the Perspective of the Triple Bottom Line

Sustainable events are managed with the aim of contributing to sustainable development through promoting inter- and intra-generational equity (Getz 2009; Hall 2012; Smith-Christensen 2009). The main objective of event sustainability is to maximize benefits whilst minimizing negative impacts, with the specific purpose of leaving a positive legacy for all stakeholders. The prevailing approach in the field of event sustainability is based on the triple bottom line framework (Elkington 1997). Sustainable events aim to balance their economic, social, and environmental impacts to positively contribute to the sustainable development of society. Thus, from the perspective of the triple bottom line, all three aspects should be considered together.

The economic impacts of events tended to be the first to be considered by practitioners and academics. Consequently, early approaches to event impacts were focused on measuring economic impacts. The success of an event itself was typically considered related primarily to its economic contribution to the hosting region (Holmes et al. 2015). The rapid rise of event tourism and the consequent benefits for the hosting community in terms of additional wealth and jobs stimulated the development and testing of increasingly accurate methods to measure this positive economic impact to the local economy (Brown et al. 2015). Further, growing scarcity of public resources served as a boost to increase attention to events' economic impacts, compelling public authorities to undertake an evaluation of cost-opportunity in funding events (Burgan and Mules 2001). More recently, some studies have highlighted that negative economic impacts can descend from the organization of an event (Chirieleison and Montrone 2013), like the indirect costs for the municipality to guarantee that the event runs smoothly (e.g., extra resources made available for policing, rubbish collection, assistance, and aid).

The social impacts of events are manifold. Some of them are definitively positive, as, for example, the effect on the sense of community

and pride for local culture and heritage (Delamere et al. 2001). Even enhanced infrastructure and revitalization of urban and rural areas can be a positive legacy of events. Besides this, numerous negative effects can arise. The "touristification" of historical commemorations, religious and folkloristic events can reduce their authenticity weakening their long-term legitimacy and even their reason to exist. Disadvantages like an increase in vandalism and criminality, traffic congestion, pressure on services, and infrastructure can reduce the quality of life for local inhabitants during the days of the event (Small 2007). Numerous methods have been proposed to evaluate events' social impacts, adopting both quantitative and qualitative analysis (Fredline et al. 2003; Kim et al. 2015).

Events' environmental impacts have been thoroughly studied only just recently, but analysis of such impacts is rapidly becoming the most spotlighted topic in this domain. Indeed, the term "green event" has become synonymous with "sustainable event" (Laing and Frost 2010; Mair and Jago 2010). The prevailing perspective is focused on measuring and reducing the event's negative impacts in terms of atmospheric and water pollution, waste, fossil energy consumption, and noise pollution (Collins and Cooper 2017). Recently, visitors' transportation choices (see ► ["Sustainable Transportation"](#)) are emerging as a key issue in terms of the negative environmental impacts attributable to events (Chirieleison and Scrucca 2017; Triantafyllidis et al. 2018; Chirieleison et al. 2020). Ecological Footprint analysis and Environmental Input–Output modeling are two of the most widely used approaches for quantitative impact assessment of events environmental externalities (Collins et al. 2009).

Managing Event Sustainability

Every event has positive and negative economic, social, and environmental impacts. Organizing special events can lead to significant advantages for the hosting community, with regard to both economic and social impacts. Nevertheless, they can also raise significant disadvantages, not least

in terms of threats to the environment. Besides the issue of a triple bottom line assessment of special events, the challenge in the last few years has become the integration of all three aspects of sustainability in one single framework, paying attention to the strict interconnections existing among them (O'Sullivan and Jackson 2002; Holmes et al. 2015; Raj and Musgrave 2009). For example, the reduction of events environmental impacts – which is highly desirable – could lead to an unsustainable increase in costs and thus to a lack of economic viability and a loss of opportunities for the local community.

Meanwhile, some characteristics of the event industry could make it challenging to deal effectively with sustainability concerns. Unlike other businesses, event organizers do not operate in the same way 365 days a year, as a special event is – by its very nature – unique and temporary. Thus, event sustainability could sound like an oxymoron, as sustainable development implies a long-term perspective, while events are meant to last a few days, or even just a few hours. In parallel, however, even if every event is different – and also the same event changes from year to the next – there are enough similarities to pursue a common management system approach in a path towards leaving a net positive legacy from a holistic perspective.

While sustainability is becoming one of the main challenges for event management, a widely accepted framework to evaluate event sustainability is still lacking. Nevertheless, the various approaches proposed by academics, professionals, standardization bodies, and practitioners share (i) a focus on promotion of the triple bottom line approach to economic, environmental, and social dimensions of events, (ii) the adoption of multiple evaluations and assessments (often based on sets of objectives and/or indicators), and (iii) a focus on a balanced contribution to society. Examples of such frameworks proposing specific performance objectives or measures include Getz (2009), Laing and Frost (2010), and Andersson and Lundberg (2013). Venue selection, visitors' transportation, supply chains, waste reduction, use of non-renewable energy, economic impacts on the

local economy, disruptions to residents, air and water emissions, cost-opportunity of public funding, stakeholder engagement, fair treatment of employees and contributors are just some of the aspects most commonly linked to event sustainability. Attention towards sustainability involves every stage of an event's life cycle: projecting, planning, staging, closing, dismantling, controlling, and feedback. A wide number of stakeholders should be involved, such as organizers, policy makers, visitors, suppliers, volunteers, local inhabitants, sponsors, and funders. While impact evaluation and monitoring are essential components of managing event sustainability, communication policies are also crucial to gain maximum benefits in terms of reputation and legitimacy.

Frameworks devoted to objective definition and evaluation of the impact aim – directly or indirectly – to promote the organization of events managed in a sustainable way (Getz and Andersson 2008). Typically, the focus is on minimizing negative social and environmental impacts while maximizing positive economic benefits. Beyond this, an alternative approach is emerging regarding event sustainability. In this second approach, events are viewed in terms of a wider significance and seen as a fruitful opportunity for promoting sustainability (Mair and Laing 2013). These events have the specific purpose not only to adopt policies and approaches which can provide a positive net impact to society but even – and foremost – to promote behavior change amongst attendees. Indeed, the event itself is used to push its audience towards more sustainable lifestyle choices. The choice of a sustainability-focused theme, the robust adoption of responsible management practices made visible through special sustainability features of the event, the staging of entertainment, and educational programs centered on sustainability: these are some of the tools used to comprehensively link the image of the event to sustainability spreading the culture of sustainability itself. Here, effectiveness is related in a large part to the adoption of communication strategies capable of capturing a broad audience and

not only visitors who are already sustainability-conscious (Tölkes and Butzmann 2018).

Event Sustainability Standards

Event sustainability standards include a wide number of national and subsector specific labels as well as authoritative international standards.

BS 8901 *Sustainability in Event Management*, released by the British Standards Institution (BSI), has been among the most influential national standards. This standard emerged from a partnership established between the 2012 London Olympics Organizing Committee and the BSI with the specific aim to elaborate a standard in the field of event sustainability. The standard, first issued in 2007, received positive reactions from the community of practitioners and began to be adopted by important events even outside the UK, for example, the United Nations Conference on Climate Change (COP15) held in Copenhagen in December 2009. BS 8901 was the precursor and model of the main standard in the field of event sustainability management, ISO 20121. Thus, following the introduction of ISO 20121, the BS 8901 standard was withdrawn.

ISO 20121 *Event sustainability management systems – Requirements with guidance for use* is a voluntary international standard for sustainable event management created by the International Organization for Standardization (ISO) in 2012. The standard has the purpose to promote the adoption of innovative solutions in the event industry for addressing sustainability issues, helping organizers to contribute to sustainable development, and leaving a positive legacy. ISO 20121 is applicable to all events, regardless of size, location, and theme and provides a practical framework to manage and reduce potentially negative social, economic, and environmental impacts of events.

Another important international standard in this field has been developed by the Global Reporting Initiative (GRI) (see ► [“Global Reporting Initiative”](#)). GRI is a nonprofit organization founded in Boston in 1997 spreading from the cooperation between the US nonprofit

organizations Coalition for Environmentally Responsible Economies (CERES) and the Tellus Institute, an interdisciplinary, nonprofit research, and policy organization mainly focused on environmental protection, with the support of the United Nations Environment Programme (UNEP). The purpose of the GRI is to help businesses, governments, and other organizations to understand, manage, and communicate their sustainability. The GRI Sustainability Reporting Standards (GRI Standards) have been continuously developed over 20 years and undoubtedly represent best practice in sustainability disclosure. Today, they are the most widely adopted global standards for sustainability reporting. Besides the Standards, GRI has also developed various Sector Disclosures containing sector-specific guidance for sustainability reporting. One of these is directed to *Events Organizers*. While in the fourth version of the Reporting Standards Guidelines (G4), the adoption of Sector Disclosures was mandatory, in the currently in force GRI Standard (which superseded G4) it is recommended, but not a requirement, for preparing a report in accordance with the Standards. The Sector Disclosure *Event Organizers*, however, still represents a landmark for sustainability disclosure in the event industry. The GRI reporting guidance *Event Organizers* covers the complete project life cycle of an event – from planning to post-event – with reference to economic, social, and environmental aspects, defining additional disclosure requirements and specific indicators to be included in the sustainability report. For every indicator, the correct data processing mode and calculation methods are provided, with specific references to definitions, compilation, and required documentation. Streamlined comparison between different events in terms of sustainability is one of the main benefits arising from this standardization of the disclosure.

Summary

Sustainable events are managed with the aim of contributing to sustainable development through promoting inter- and intergenerational equity. The

main objective of event sustainability is to maximize benefits while minimizing negative impacts, with the specific purpose of leaving a positive legacy for all stakeholders. The prevailing approach is based on the triple bottom line framework and takes into account the economic, socio-cultural, and environmental impacts of events on the hosting community.

[Food design innovation](#); [Sustainable design in innovative food production](#); [Sustainable innovation in food design](#)

Definition

Innovation is the process of renewal of science and technology for economic and social benefit (Rinkinen and Harmaakorpi 2018). It refers to both a process and a result. It can be handled in four main types such as product, process, marketing, and organization (Ramirez et al. 2018). Food innovation, on the other hand, can be defined as the completion of all the innovation and development work carried out for food production, distribution, sales, consumption, and waste management. Therefore, innovation is one of the main routes through which the food industry can increase productivity and gain a competitive edge in the global marketplace (Kaleka and Morgan 2017). The scope of innovation is very wide and it is possible to interpret it differently for each

group of food products. Moreover, innovation in food can also be discussed through a variety of subcategories, from the use of sustainable techniques to ergonomic food designs and even consumption. It is also not possible to consider the concept of food design separately from sustainability and the sustainability concept separately from innovation. In this sense, the terms food design and innovation are intrinsically associated (Elias and Marsh 2020). Within the scope of this chapter, sustainability will be explained in the context of the food industry innovation. In addition, different fields of innovation will be evaluated together with the sustainable food design approach.

Introduction

Design and innovation for food sustainability began to get attention in the mid-1980s. By the early 1990s, a group of research-motivated designers and academics had emerged in Europe and the USA (Rao et al. 2001; Akça 2018). The leading activity in this field was initially called green design. Green design focuses on improving only one feature of a product, or concentrates on a food product's appearance (Zhihong and Yucheng 2000; Ala-Harja and Helo 2014). Examples of green design include the use of natural food colorants instead of artificial ones, or the use of recycled materials for food packaging. Since a food product may sometimes have at least one sustainable feature, this is enough to call it a sustainable product. However, this does not mean that a food product then meets all the sustainability principles. Changing a single feature of a food product may reduce its negative impact on the environment and society only in small amounts, or not at all (Lindgren et al. 2018). Hence, it is clear that the food industry needs to work hard on sustainable food product design and innovation in order to meet the sustainability criteria (Ciccullo et al. 2020).

From the point of view of the food industry, the term innovation is used to define a reduction in costs, an increase in profitability in a sustainable manner, and/or the achievement of a certain

quality in food products. The innovation provides an advantage to the company in managing the production processes. By its nature, therefore, innovation in food production brings economic development coming mainly from power of food market (Olsen 2015; Busse and Siebert 2018).

In the food market, competition issues have attracted increasing interest from policymakers and food professionals in recent years. Therefore, greater attention should be paid to the functioning of food markets in relation to the role of competition in ensuring food design and innovation to follow sustainability requirements. Hence, the competition in the food and beverage industry is increasingly competitive (Voytovych and Polyak 2019). In today's competitive environment, it is becoming more and more difficult for such businesses to survive only by imitating the activities of their rivals. Therefore, competition in the industry is leading to new products being developed. As part of this, food and beverage businesses have focused on processing consumer-oriented high-quality food products rather than expensive and uniform offerings (Lusk and McCluskey 2018). However, the share of resources allocated to R&D in the industry has to increase in order for the industry to compete globally. Although it has increased in recent years, capacity utilization in the food and beverage industry is still not at the desired level (Bayona-Saez et al. 2017). The reason for this may be a lack of suitable raw materials, insufficient technical knowledge, lack of capital, or production and sales problems

(Fetullah 2012). Therefore, in order to achieve economic development, it is necessary to match innovation with demands and needs, ensure effective coordination with the agriculture industry, and to produce goods without sacrificing quality.

Innovation is a way that food businesses can survive, take advantage of opportunities, and increase their competitiveness (Belous 2013). Figure 1 schematizes the process from the idea stage of a food product to its place in the market. As can be seen, design adds value to the process, with innovation considered primarily at the outset, with the whole process proceeding in line with the principle of sustainability.

The use of innovation enables food production to be planned and to be flexible depending on the technology available and on consumer needs. At this point, design enters the circuit. Design includes a number of elements, such as how the food is produced from raw materials, product shape and size, food packaging, and how it is served. In other words, food design has always been a factor underlying the whole process, since it came more to the forefront as the concepts of innovation and sustainability started to have an impact on production processes (Messerli et al. 2019; Tukker et al. 2017). Today, food design has evolved and has increased its impact on physical and sensory characteristics of food such as appearance, smell, taste, and texture (McCrickerd and Forde 2016). The important message is that food design and design innovation approaches come within the scope of sustainability. Therefore, the

Sustainable Food Design and Innovation, Fig. 1 Sustainable innovative design process for a food product (yellow: innovation dominated areas, blue: design

dominated areas, green: innovation and design dominated areas) (Kernbach and Nabergoj 2018)

food industry provides a forum in which the topics of sustainability, innovation, research and development, design, and competitive advantage can be evaluated.

Sustainable Food

People have always needed to meet their existential needs. By doing so, they had more or less food alternatives depending on the conditions of the era and the time they had to process foods. Moreover, since the dawn of existence of society, the food industry has been an agent of cultural development. Food design is a feature of all civilizations and forms the basis of different gastro-cultural structures (Heitmann et al. 2011). For this reason, it is possible to reveal many food designs reflecting different cultural and technological accumulations in a multidisciplinary sense. At this point, food can be considered as an indispensable element in design (Biderman 2017). Today, where food has such an important place, resources must be used efficiently while producing food, to protect the environment and the ecosystem, and to pass on technological knowledge from one generation to another. This is also covered by the concept of sustainability (Ibrahim et al. 2019). Although the concept can be generally applied, it is possible to see how it relates to different areas specifically (Fig. 2).

In Fig. 2, application areas on food sustainability are linked. In this context, it is noteworthy that the food industry has a tightly interconnected cosmopolitan structure. For example, it can be seen that the distribution of agricultural resources, labor management, the distribution of the labor force in the parameters of the demographic characteristics of the society, natural resource management, social responsibility studies, the association of food safety principles with culture, the impact of supply chain management on food safety, and consumer preferences to control global trends, innovation, environmental awareness, production efficiency, and many more elements have a role in the formation of the food cycle within the scope of food sustainability (Morone et al. 2019).

Similarly, since the food industry has many sub-branches such as meat and meat products,

dairy products, seafood products, bakery products, fruit and vegetable processing, vegetable oil and vegetable oil products, sugar industry products, pastry products, feed manufacturing, and other food products (Nikmaram and Rosentrater 2019). Therefore, the concept of sustainability can serve the same purpose in many areas of the industry (Lang and Barling 2012; Aiking and De Boer 2004). The concept itself is based on three fundamental dimensions such as economic, environmental, and social and is related to the implementation of innovative methods and principles that include developments in the food industry (Voytovych and Polyak 2019; Giddings et al. 2002). In this respect, food manufacturers are engaged in various activities to increase their production efficiency. As a result of interaction between sub-branches of the food industry, sustainable development has become a key issue in the food industry. Its principles of trying to ensure the welfare and productivity of the community in industrial production have contributed to an increase in consumer awareness about food consumption over time (Peano et al. 2019). Moreover, sustainability in food production is also critical to food safety and economic development. Food safety encompasses the whole process of production, from the raw materials to consumer consumption. Therefore, it has many variables, such as the quality of the raw materials used; hygiene on the production line; the positioning of equipment; prevention of cross-contamination; consistency in the product supply chain; and consumption. The economic dimension of sustainable development in the food industry, starting with a country's existing technical facilities and resource management, evaluates all activities from the perspective of issues such as income levels of labor, transfer of information from stakeholders in the industry, and improvement of the welfare of the country. It can therefore be inferred that the concept of sustainability can be applied to all areas of the food industry (Lubin and Esty 2010).

Innovation

Although there are a number of approaches that do not regard innovation as a concept in itself, it can

Sustainable Food Design and Innovation, Fig. 2 Comprehensiveness of the food sustainability (Eakin et al. 2017)

be stated that innovation is one of the most important factors in a company's success (Baregheh et al. 2009). Generally defined as the process of transforming innovative ideas into value-added outputs, it can be clearly understood by considering it as the implementation of new ideas, services, processes, and business models in order to create new, better-quality food products (Camisón and Villar-López 2014; Shepherd and Ahmed 2000).

Types of Innovation

It is not possible to assign the concept of innovation to a specific food field. The concept of innovation has a wide range of applications as well as a variety of food application areas. In order to be efficient in matching in the field of food and innovation, the concept of innovation can be

evaluated in four categories (Soto-Acosta et al. 2016) (Fig. 3).

These four categories are identified as follows (Ramirez et al. 2018; Oke 2007):

- Product innovation
- Process innovation
- Marketing innovation
- Organizational innovation

By following through with innovations in each of these areas, a food business can make sustainable production improvements.

Product Innovation Product innovation is the improvement of the current specifications of products or services, or the introduction of new products or services. It covers all changes made to the

Sustainable Food Design and Innovation,

Fig. 3 Types of innovation

components or materials and equipment and to the user-oriented characteristics of the food product (Bloch 2007). For example, being a functional food, lactose-reduced milk or lactose-free milk for special nutritional purposes can be considered in this context. This product has been developed to prevent digestive disorders experienced when milk is drunk by consumers with lactose intolerance. It is possible to reduce bloating and gas complaints after consuming the product, as the milk sugar is broken down during the packaging phase with the natural lactase enzyme it contains (Ohlsson et al. 2017).

Process Innovation Process innovation is the name given to comprehensive innovations in the production method, including logistics processes. It also includes technological and software changes related to the technical infrastructure (Ramirez et al. 2018; Bloch 2007). One of the most striking examples of this is the Ford assembly line where production time was reduced from 12 h to 90 min per product. In the food field, freeze drying, one of the storage methods, can be considered within the scope of process innovation. Freeze drying takes place by first freezing the product, then lowering the pressure in the environment, and evaporating the water it contains before it becomes liquid. Meanwhile, most of the chemical and physical properties of the product are preserved. The fact that the process takes place

in completely closed and hygienic conditions is another advantage of the technique in terms of product quality and safety. In this way, it is advantageous for consumers who prefer organic, additive free, and hygienic foods such as fresh fruits and unprocessed foods (Duan et al. 2016).

Marketing Innovation Marketing innovation is a new marketing method that includes significant changes in product design, product positioning, product promotion, or pricing (Bloch 2007). Marketing innovation aims at increasing the sales of a company, responding to customer needs more successfully, and opening new markets or positioning a product in the market in a new way. For example, the name of the IKEA brand has often been associated with innovation. As the founder of the world of ready-to-assemble furniture products, IKEA has a wide product portfolio from food to furniture, from kitchen utensils to office supplies. When it comes to marketing innovation examples, it is one of the first companies that come to mind. Approaching its target audience with augmented reality technology in 2013, the company provided access to all its products. With its catalog application, the brand, which provides an effective service on how IKEA products will look in the living space of its target audience, has achieved a significant increase in product sales and has become one of the successful marketing innovation examples (Tronvoll et al. 2019).

Organizational Innovation Organizational innovation refers to improvements made to the structural, managerial, internal, and external relations of companies and organizations (Anzola-Román et al. 2018). For example, if the flow of information between employees causes delays or misunderstandings, an initiative may be implemented to ensure that employees have easy access to necessary information. The creation of a data network in a company that can be used by employees is an example of an organizational innovation. Another method supporting the concept of organizational innovation is the KAIZEN approach, which means continuous improvement (Suárez-Barraza et al. 2012; Paul Brunet and New 2003). The Kaizen approach emphasizes the necessity of staging interventions to achieve success. Time is the key criterion in this. When time is chosen as the improvement parameter, the process should be monitored accurately and carefully.

The Importance of Innovation and its Relationship with Sustainable Competitive Advantage
From the perspective of the food industry, customer demand dictates innovation rather than simply trying to reduce production costs (Liao and Tsai 2019). An example of this is the healthy snack industry. The market share of healthy

snacks has been increasing over time in the functional food market, which is developing rapidly alongside society's greater understanding of healthier nutrition (Vecchio and Cavallo 2019). When healthy snacks were first produced, customers judged them only on taste, color, and shape of the packaging (Togawa et al. 2019). Today, it is quite different due to the rapid expansion of the food product range. Since consumers can buy these products within approximately the same cost range, they can demand additional specifications (Crofton and Scannell 2020). Their demands may result in product improvements, such as biodegradable packaging.

The food industry is very competitive (Yang and Nie 2017). Companies need to consider operational efficiency while fulfilling the demands of customers. In this context, they try to provide high-quality products efficiently without creating waste. All of these efforts result in effective innovation outputs at the end of the food production cycle. Therefore, it is clear that companies need innovation in order to get a competitive advantage (Anzola-Román et al. 2018; Soto-Acosta et al. 2016; Ireland and Webb 2007). The importance and advantage of innovation for companies, whether they are food businesses or not, can be summarized as the relationship between the factors set out in Fig. 4.

Sustainable Food Design and Innovation,

Fig. 4 Factors affecting sustainable competitive advantage (Hancıoğlu and Türkoğlu 2017)

In a globalized world, it is possible to gain a competitive advantage by creating the greatest additional value with minimum input. The best way to do this is innovation. Innovation from different perspectives (product, process, marketing, and organizational) will also serve sustainability in production. This can be achieved with sustainability-oriented innovation such as finding an innovative solution to disruption in a food product or production. Polyethylene (PE) material provides impermeability in paper-based food packaging materials and is used for consumption of beverages such as tea and coffee. Just as PE is not recyclable in nature, a PE-coated paper-based packaging material cannot also be recycled in nature. Unfortunately, this situation is contrary to the principles of sustainability in terms of environmental protection. The problem can be solved by coating the mentioned packaging materials instead of using PE with another biodegradable material, such as a bio-based lack, without compromising the quality of the packaging. This is an example of product and process innovation that can be given to the principle of sustainability. Thus, the paper packaging will be recycled many times by contributing to environmental protection and by avoiding depositing the PE-coated paper-based

packaging materials in the environment as waste (Al-Tayyar et al. 2020).

Sustainability-oriented innovation brings a sustainable competitive advantage. Some of the advantages are maintained against competitors over a long time, while others can be immediately imitated (Lev 2017). Building the competitive advantage in this sense means building a wall around the company's position in a retail market (Lubit 2001). Establishing a sustainable competitive advantage will provide long-term financial returns to businesses. One of the determining factors in winning a competitive advantage in the food industry is whether a product is original and whether it can be easily imitated. Another decisive factor is how well an innovation can be implemented. Both have a positive and meaningful effect on sustainable competitive advantage. Moreover, competitiveness is not a static but a dynamic phenomenon (Fig. 5).

For retailers, the easiest way to differentiate themselves is to satisfy customers' needs and desires better than their competitors. The term customer satisfaction is different from customer service. Customer satisfaction is determined by whether the total shopping experience meets or exceeds customer expectations. It is the main determinant of customer loyalty and customer

Sustainable Food Design and Innovation,

Fig. 5 The relationship between innovation, competitiveness, and productivity increase (Gupta et al. 2016)

retention and the creation of a valuable business organization (Novelli et al. 2006).

The majority of studies in this area have examined the food processing industry whereas there is little research on the relationship between innovation and sustainable competitive advantage in the service sector. In fact, this whole area has been hitherto neglected in the food and beverage industry (Mention 2011; Novelli et al. 2006).

Research and Development (R&D)

Research and development (R&D) is a systematic and creative work that is carried out to increase knowledge for use in new applications (Maruszewska and Strojek-Filus 2020). R&D helps businesses to focus on innovation. In the case of the food industry, R&D is considered a necessary resource for developing new food products, production techniques, and processes. The information obtained as a result of these activities is used for the creation of new markets, as well as for the development of new food products and production methods and is, therefore, a major factor in encouraging innovation and increasing competitiveness (Ferreira et al. 2017). Nowadays, R&D in the food industry is just as important as it is in any other industry. In fact, R&D awareness in industry generally tends to be more developed currently than in previous eras and is a key component of a country's economic growth (Wang et al. 2018). This awareness creates an opportunity for R&D to play an important role in innovative product design, which is increasingly necessary for success. In addition, the accumulation of technical and organizational knowledge as part of the R&D process helps to develop strategies for managing consumer behavior. Technical know-how increases the quality of food, while providing new products in response to changing consumption behaviors, thus providing competitive power to the food company (Soon and Saguy 2017). As a result of R&D activities, by reducing costs and ensuring product differentiation and quality, competitiveness is gained in price and in other product specifications. In other words, R&D can be regarded as an important tool for food

producers to gain a niche in the market or to increase their market share in the global competitive environment (Schot and Steinmueller 2018).

Food Design

Food design is both a way of symbolizing a technical and aesthetic style and a way of differentiating a product. It also includes the processes used to solve problems and evaluate solutions proposed in the food production system (Namany et al. 2019). The most important point of food design, which brings together many fields of expertise, is to develop a product so that it can be obtained easily and cheaply without decreasing its nutritional value, while at the same time presenting it in a way that gives people happiness and pleasure.

Manufacturers are actually quite flexible and successful in keeping up with changes in the industry and responding to different consumer demands (Chan et al. 2017). It may be possible for a food product to quickly stand out among its competitors if it is practical, easy to transport, easy to store, and complies with regulatory standards (Kaleka and Morgan 2017). Today, businesses are looking for ways to establish an emotional relationship between the product and the consumer. Design can be considered as one of the tools in which this relationship can be established (Biderman 2017). Successful designs incorporate products and services that enhance the consumer's experience. In addition, fragmented markets force manufacturers to continually improve themselves in producing new models. The design is part of this process (Jagtap and Duong 2019).

Designers seek to offer more competitive products to customers by differentiating them on the basis of their aesthetic characteristics. Design is a competitive advantage that can be implemented in any industry. However, a systematic approach should be followed in order to gain a competitive advantage through design activities. Therefore, the competitive strategy of the company should firstly be clearly determined (Spink 2019). Next, design needs must be aligned with the company's strategy for remaining competitive. The design should include a product-specific approach, and

Sustainable Food Design and Innovation,

Fig. 6 Design ladder model (Doherty et al. 2014)

consider data related to the product to be designed and environmental factors. Therefore, the company's design team will need to be in constant contact with other technical, financial, and management departments, depending on the nature of the product. This provides competitive advantage. Hence, design is a process that requires a systematic, planned approach (Fig. 6) (Biderman 2017).

In the model set out in Fig. 6, there are four steps in total. In the first step, there is no awareness or planning or expertise with regard to design management. No resources have been allocated or processes created. In the second step, design management is considered as a product development project. At this stage, although awareness about design management is higher than the previous stage, the limited resources within the institution and the lack of regular communication among the departments signal that the processes have not yet been planned. In the third step, design management begins to be seen as part of the whole operation. Compared to the previous steps, communication between departments within the organization operates in a more planned way, while awareness levels and relationships between those responsible for production are moving towards a professional understanding. In addition, in this step, production is no longer product oriented. A process management approach is more evident than in the previous steps. In the last step, design management has started to become one of the important elements of the institution and at the center of many initiatives. Although the specialists working in the institution work in

different departments, they all have a certain knowledge of design. In this way, many other issues, such as financial management, access to resources, production, and efficiency analysis, are evaluated under the title of design management by specialists and the process is carried out in a planned manner (Bisantz et al. 2003).

In addition to the managerial approaches mentioned in respect of the concept of design, it is also useful to divide the food design concept into sub-disciplines, such as food design and food product design, and to explain the importance of design for food innovation. The concept of food design can be seen as a bridge between food and design. It can also be used to address different approaches to food in the innovation model (Zampollo 2016). Here, the concept of design is apparent to the producer and consumer at every stage, from production to consumption, from conservation to waste disposal. Food product design can be interpreted as handling the concept of food design on a more technical basis (Moskowitz et al. 2012). The aim here is to design new food product types on a scale that can be industrially produced. In other words, food product design relates to foods that are suitable for mass production, such as chocolate, pasta, and snack foods. The relationship between the unit operation process parameters applied to foods are examined in any new design of food properties. Among the parameters taken into consideration are melting, boiling, foaming, and mixing. The aim is to transform the qualities of the product in terms of temperature, color, texture, or stability in a way that will differ from previous versions.

Sustainable Food Design and Innovation,

Fig. 7 Impact of design, innovation, and sustainability on competitiveness (Ferreira et al. 2017)

Unifying Factors Playing a Role in Achieving Competitiveness

The World Economic Forum has defined competitiveness as a business's superiority over their competitors in designing, producing, and pricing products and/or services (Gómez-Vega and Picazo-Tadeo 2019). In order to ensure efficiency in competition, factors related to the concept such as information infrastructure, production structure, policy, consumer demand structure, and corporate formation should be managed in an integrated manner (Fig. 7). As can be seen from the figure, the prominent factors to achieve successful competitiveness in food industry can be specified as sustainability, food design, and innovation (Berti and Mulligan 2016). Successful management of these three factors at both the pilot- and industrial-scale food productions will result in sustainable food innovation and, therefore, competitiveness.

Successful food production design also takes part among these factors at both the pilot and industrial scale, allowing for sustainable process innovation and, therefore, competitiveness. The competitiveness depends on many factors, such as R&D activities, industrial performance, the foreign trade surplus of countries, the availability of high-tech products, and the use of trained

human resources. It can be said that in order to gain competitiveness, all the resources of the enterprise should be brought together and effectively used.

Therefore, competitiveness within the scope of the food industry can be defined within the framework of increasing the living standards of society due to increases in food productivity, and by its contribution to the social welfare and competitiveness by forming a balancing harmony among the factors that are stated in Fig. 2 (Bredahl 2019). When these factors that take part in competitiveness are in harmony with each other, productivity increases and the industry can accelerate if there is efficient use of the country's export capabilities and natural resources (Sonmez Cakir and Adiguzel 2020). In other words, the ultimate goal of the competition strategy should be to comply with the competition rules and to change these rules for the benefit of the food business (Molden 2013). For example, if it is desired to develop an innovative food in a sustainable framework, the competencies of the enterprise in terms of corporate formation should be reviewed. Afterwards, consumer demands for this innovative approach are confirmed by conducting a market research. If there is a need for the product, the structure of production line within the enterprise is

reevaluated with a sustainability approach. In this regard, while the food is being produced, the design factors in the product itself and its production are applied. All steps from the production of the product to the consumer and even the disposal of waste are evaluated within the framework of sustainability. In this way, the concept of competitiveness arises for food production (Lev 2017; Ferreira et al. 2017).

Summary

Today, the concepts of design and innovation for sustainability in the food industry are a combination of small- and large-scale, short- and long-term, and technological and social innovations and improvements. These are important elements that create bridges in many areas, such as transportation, energy, agriculture, strategic planning, and implementation in the production processes planned to increase the welfare level of society. The current chapter emphasizes that food innovation positively and significantly affects sustainable competitive food advantages. In this context, it can be said that food businesses can achieve a sustainable competitive advantage through innovation, which plays a very important role in achieving production sustainability. It can be realized through innovations that increase customer satisfaction with regard to standard recipes of existing food products, innovations that increase food quality in existing products, and innovations that reduce raw material and production costs. In addition, effective design of food and food processes and the effective distribution of food are among the most important factors in achieving sustainability and effective productivity. The area of design and innovation for sustainability touches many food production areas, and the ability to organize and to manage these activities from a strategic perspective within the framework of the transformation of socio-technical systems reflects the knowledge and cultural level of the industry.

Definition/Description

Daly and Costanza argue, based on their analyses, that the concept of “sustainable growth” is a bad oxymoron which should be rejected (Costanza and Daly 1992; Daly 1990, 2010). Other

researchers have defined the concept in various ways. Traditionally, sustainable growth reflects the view of very weak sustainability position. It has meant the realistically achievable growth that a company or national economy could maintain without running into problems (MBN 2018). Today the term has two positions: weak and strong sustainability. Based on the neoclassical weak sustainability position, sustainable growth can continue as long as utility is not declined, the reduction of natural resources are replenished by the increase of the natural or produced resources (Turner 1993; Neumayer 2003), and the negative impact on environment is compensated by innovative technologies (Turner 1993). When the concept of sustainable growth is used by environmentalists and advocates a variant of strong sustainability position (Pezzey and Toman 2005; Turner 1993), the concept is seen as a synonym of economic growth (MBN 2018). They stress that sustainable growth can continue over the long term if intolerable pollution is not created or all the nonrenewable resources are not used up. In ecological sustainability (the second variant of strong sustainability position, Pezzey and Toman 2005; Turner 1993), it emphasized environmental protection in a global ecological, socioeconomic, and political context (Sharpley 2000). In this connection, the concept of sustainable growth means growth that is repeatable, ethical, and responsible to, and for, current and future communities (Miller 2018).

Introduction

All economic activity ultimately depends on services provided by nature. Business and the finance industry are starting to question how global environmental risks will affect the macroeconomic performance of countries, sectors, and financial markets, and policy-makers wonder how human beings will meet climate and sustainable development targets with declining nature and biodiversity. One major focal point is the rapid depletion of nonrenewable resources, especially fossil fuels, on which manufacturing is greatly dependent. However, not only nonrenewable

resources are in decline. While climate change is a growing threat, the main drivers of biodiversity decline continue to be the overexploitation of species, agriculture, and land conversion. The Living Planet Index has recorded an overall decline of 60% in species population sizes between 1970 and 2014 (Grooten and Almond 2018, p. 11). Although water scarcity is already a reality for some countries, it might even worsen due to the expected population growth and the resulting increase in production and consumption. This unsustainable lifestyle has led to the “ecological overshoot.” The term is used to describe when, at a global level, the ecological footprint is larger than biocapacity (WWF 2012, p. 8).

As scenarios illustrate, these trends will likely continue in the future if research results are not taken into account. In a business-as-usual scenario, global extraction of natural resources could further grow by more than 50% by 2030 compared to today’s situation (Giljum and Polzin 2009), and by 2050, humanity would require an equivalent of 2.9 planets to support the “business-as-usual” assumptions (WWF 2012, p. 100). With the phrase “business as usual,” it is referred to the normal conduct of business regardless of circumstances which pose a potential negative impact (BusinessDictionary 2018a).

The Brundtland Commission Report (WCED 1987) has made a great contribution by emphasizing the importance of sustainable development and in effect forcing it to the top of the agenda of the United Nations and the multilateral development banks. According to Daly (1990), the report addresses sustainable growth even if it does not use that concept. He argues that the concepts sustainable growth and sustainable development contradict one another, and therefore the concept of sustainable growth should be rejected as a bad oxymoron. He justifies his view stating that since the human economy is a subsystem of a finite global ecosystem which does not grow, even though it does develop, it is clear that the growth of the economy cannot be sustainable over long periods of time (Daly 1990).

Other researchers have put forward different views on the concept. The traditional definition

of the concept of “sustainable growth” expresses the ideas of “business as usual.” Sustainable growth means the realistically achievable growth that a company or national economy could maintain without running into problems (MBN 2018). The more modern definitions of the concept are based on environmental and ethical issues. The same core idea of intergenerational equity that future generations are entitled to at least as good a quality of life as the current generation has can be found from their background (Pezzey 1992). Otherwise, the conceptual definitions differ depending on the financial perspectives and the environmental and social perspectives underlying them.

Key Issues

The concept of “sustainable growth” is a controversial one. Researchers are disagreeing about what the concept of sustainable growth means and whether it can be used at all. Herman E. Daly discussed in his Commentary article “Towards some operational principles of sustainable development” the concepts of “sustainable growth” and “sustainable development” making distinction between the terms growth and development (Daly 1990). According to him, to grow means “to increase naturally in size by the addition of material through assimilation or accretion,” and to develop means “to expand or realize the potentialities of; bring gradually to a fuller, greater, or better state” (p. 1). Growth is thus a quantitative increase in physical scale, while development is the qualitative improvement or unfolding of potentialities.

Daly also argued that an economy can grow without developing, or develop without growing, or do both or neither. Based on his discussions, he concluded that “since the human economy is a subsystem of a finite global ecosystem which does not grow, even though it does develop, it is clear that growth of the economy cannot be sustainable over long periods of time” (Daly 1990, p. 1). Two years later, he and Costanza defined the concepts of growth and development. They stated that the former one means material increase in size

and the latter one improvement in organization without size change. Given these definitions, they concluded that growth cannot be sustainable indefinitely on a finite planet and that development may be sustainable within the given limits (Costanza and Daly 1992).

Later on Daly wrote (2010, p. 11):

Impossibility statements are the very foundation of science. ...By respecting impossibility theorems we avoid wasting resources on projects that are bound to fail. Therefore economists should be very interested in impossibility theorems, especially the one to be demonstrated here, namely that it is impossible for the world economy to grow its way out of poverty and environmental degradation. In other words, sustainable growth is impossible.

The conclusion of Daly’s and Costanza’s dictionary-based discussions is that the concept of “sustainable growth” should be rejected as a bad oxymoron (Costanza and Daly 1992; Daly 1990, 2010).

Other researchers have put forward different views giving various definitions to the concept (Table 1). The traditional definition of the concept “sustainable growth” reflects the technocentric and anthropocentric perspectives and very weak sustainability position. According to it, sustainable growth means the realistically achievable

growth that a company or national economy could maintain without running into problems (MBN 2018). It also means the right of the current generation to use nature and unfettered free market (Davies 2013). Growth is imperative for corporate success (Blanco and Sheffi 2015). There is clearly a trade-off between rapid economic growth today and growth in the future (Sequoia 2018). Rapid growth today may, however, exhaust resources and create environmental problems for current and future generations. People confront, e.g., the simultaneous challenges of growing disruption of the global climate, the depletion of vital resources such as fresh water and oil, and the massive and rapid extinction of animal and plant species around the world (Elgin 2010). Thus, the growth based on the view of very weak sustainability position is not sustainable.

The more modern definitions of the concept of “sustainable growth” include different views about its conceptual content and meaning reflecting the ideas of weak or strong sustainability position. Almost all approaches to sustainable growth or sustainable development contain the same core ethic of intergenerational equity that future generations are entitled to at least as good

Sustainable Growth, Table 1 Definitions of sustainable growth

Definitions	References
“Sustainable growth, traditionally, has meant the realistically achievable growth that a company or national economy could maintain without running into problems.”	MBN (2018)
“Sustainable growth is growth that can be maintained without exhausting future resources. There is a trade-off between rapid growth today and growth in the future; rapid growth today may exhaust the addressable market and make it impossible to sustain your product over a longer period of time.”	Sequoia (2018)
“Today the term sustainable growth is frequently used by environmentalists, meaning economic growth that can continue over the long term without creating intolerable pollution or using up all the non-renewable resources.”	MBN (2018)
“Sustainable growth means the level of growth that can be sustained (environmentally, economically and otherwise). . . . many authors writing on sustainability today presume that growth runs counter to sustainability, especially to the growth of population and to the economic growth (defined by standard economic measures such as GDP).”	Božuć (2015, p. 29)
Sustainable growth comprises next elements: Building up a competitive, low-emission economy; environmental protection; developing new, environmentally friendly technologies and methods of production; installation of efficient and “smart” energy networks; improving the conditions for the development of entrepreneurship; and supporting customers in making informed choices	EC (2018a)
“Sustainable growth means growth that is repeatable, ethical and responsible to, and for, current and future communities. It’s key to the long-term success of any business.”	Miller (2018)

a quality of life as the current generation has (Pezzey 1992). Unlike Davies (2013), Pezzey (1992) argued that one important part of sustainability not covered by the core ethic is that of intragenerational equity.

Different perspectives of sustainability have now been considered from the extreme anthropocentric to the extreme bio- or ecocentric positions, which are related to the criteria of very weak, weak, strong, and very strong sustainability. Very weak sustainability and weak sustainability have technocentric and anthropocentric perspectives based on the works of two neoclassical economists: Solow (1986, 1993) and Hartwick (1977, 1978). Based on the neoclassical views, it can be stated that sustainable growth can continue as long as total capital stock (utility) is not declined, the reduction of natural resources are replenished by the increase of the natural or produced resources (Turner 1993; Neumayer 2003), and the negative impact on environment is compensated by innovative technologies (Turner 1993). Sustainable growth can continue with free market focusing on produced capital (Davies 2013). The problem with this kind of views is that the resources that are most threatened are those without markets, for example, the receiving capacities of the oceans, atmosphere, and stratosphere and the greater part of the world's biological diversity (Pearce et al. 1994).

In environmental sustainability (a variant of strong sustainability position, Pezzey and Toman 2005; Turner 1993), the concept of "sustainable growth" is seen as a synonym of economic growth (MBN 2018). It is stressed that sustainable growth can continue over the long term if intolerable pollution is not created or all the nonrenewable resources are not used up. So, it is seen that sustainable growth is depending on environmental sustainability, and it is thus important to take into account such factors and practices which affect the quality of the environment (BusinessDictionary 2018b), the economic activities, and the quality of life of people on a long-term basis (Elkington 1994). The basic ideas behind environmentalism dictate that corporations have responsibilities that go beyond the

production of goods and services. These responsibilities involve helping to solve important social problems, especially those they have helped create (Peattie 1995). In the global economy, businesses ideas such as corporate social responsibility and socially responsible investment are gaining in importance (Janicka 2016). Corporate social responsibility is the responsibility of enterprises for their impact on society (EC 2017). Socially responsible investing is a strategy for investing individual- or institution-owned funds, which equally strive to maximize profits in achieving the social good (Grupa Lotos 2017).

In ecological sustainability (the second variant of strong sustainability position, Pezzey and Toman 2005; Turner 1993), it is stressed that sustainable development requires environmental protection in a global ecological, socioeconomic, and political context (Sharpley 2000). This idea is based on the phrase "triple bottom line" which was first articulated by Freer Spreckley in 1981 in his publication called *Social Audit – A Management Tool for Co-operative Working*. In this work, he argued that enterprises should measure and report on financial performance, social wealth creation, and environmental responsibility. Later on, the phrase "triple bottom line" was articulated more fully by John Elkington in 1994 and 1997. Elkington presented that businesses need to measure their success not only by the traditional bottom line of financial performance (profits, return on investment, or shareholder value) but also by their impact on the broader economy, the environment, and the society in which they operate (Elkington 1997, 1998).

Savitz and Weber added their perspective on the term sustainable growth in 2006 in their book, called *The Triple Bottom Line*, which advocates for a balanced focus on profit, people, and the planet. In its opening pages, they defined a sustainable corporation as one "that creates profit for its stakeholders while protecting the environment and improving the lives of those with whom it interacts." A sustainable corporation thus operates so that its business interests and the interests of environment and society intersect and benefits flow naturally to all stakeholders, including

Sustainable Growth, Fig. 1 The sustainability sweet spot. (Based on Savitz and Weber 2006)

employees, customers, business partners, the communities in which it operates, and its shareholders (Savitz and Weber 2006). This common ground of business is what they call the sustainability sweet spot (Fig. 1): “the place where the pursuit of profit blends seamlessly with the pursuit of the common good” (p. 21).

It is stressed today that sustainable growth is based on ecologically, socially, and ethically justified solutions (Ministry of Economic Affairs and Employment 2018). Sustainable growth means growth that is repeatable, ethical, and responsible to, and for, current and future communities (Miller 2018). According to the EC (European Commission), sustainable growth comprises the following elements (EC 2018a):

- Building up a competitive, low-emission economy that uses resources in rational and economical manner
- Environmental protection, including mainly the reduction of greenhouse gas emissions and preventing the loss of biodiversity
- Developing new, environmentally friendly technologies and methods of production
- Installation of efficient and “smart” energy networks, which will give additional competitive advantage to European business
- Improving the conditions for the development of entrepreneurship
- Supporting customers in making informed choices

EC has identified five main targets which should be accomplished by 2020 (EC 2018b):

- Employment
 - 75% of people aged 20–64 to be in work
- Research and development (R&D)
 - 3% of the EU’s GDP to be invested in R&D
- Climate change and energy
 - Greenhouse gas emissions 20% lower than 1990 levels
 - 20% of energy coming from renewables
 - 20% increase in energy efficiency
- Education
 - Rates of early school leavers below 10%
 - At least 40% of people aged 30–34 having completed higher education
- Poverty and social exclusion
 - At least 20 million fewer people in – or at risk of – poverty/social exclusion

The analysis of the above elements and targets indicates that current EU priorities focus on environmental protection, developing conditions conducive to the improvement of EU citizens’ knowledge and skills (leading to higher employment and reduced poverty), and business competitiveness (cf. Janicka 2016). These focuses are in line with the milestones of ecological sustainability which are eco-efficiency, eco-equity, and eco-effectiveness (Dyllick and Hockerts 2002). Eco-efficiency is focused on economic activity with regard to nature’s goods and services and stresses fundamental changes in the way societies produce and consume resources (UN 2009). Eco-equity stresses the equal rights of all peoples to environmental resources and social responsibility of the current generation for the future generations (Economics Online 2018). Eco-effectiveness in its part seeks solutions for ecological problems (UN 2009). It also has requirements concerning a shift of mindset and transformation of business models (Brooke 2000). One of the key business strategies for sustainable growth has taken the shape of green marketing. Green marketing is a business strategy where companies have concern for environmental protection and practice green

philosophy to run their marketing activities (Saxena and Khandelwal 2010).

Summary

In recent decades, global concern has emerged about the nonrenewability of natural resources as a factor limiting production and the threat to long-term economic growth caused by environmental destabilization and pollution. So, financial markets have started to realize the need to take into account an environmentally friendly approach and aspects of sustainable growth in their investment decisions. The difficult problem to be solved is how sustainable growth can be achieved, especially as the perceptions of researchers concerning the concept differ. Some scientists, e.g., Daly and Costanza, have argued that the whole concept must be rejected as a bad oxymoron. Others have considered it usable, but defined it differently depending on the starting points and perspectives.

Based on the neoclassical views, sustainable growth can continue as long as total capital stock is not declined, the reduction of natural resources is replenished by the increase of the natural or produced resources, and the negative impact on environment is compensated by innovative technologies. In strong sustainability position, environmentalists see the concept as a synonym of economic growth, and advocates of ecological sustainability in their part think that sustainable growth means growth that is repeatable, ethical, and responsible to, and for, current and future communities. The key issues in the contents and objectives defined by the European Commission for sustainable growth are environmental protection, improving the EU citizens' knowledge and skills and maintaining economic competitiveness.

Sustainable Growth Cycle

► Lifecycle of Sustainable Development

Sustainable Happiness

Xavier Landes

Stockholm School of Economics in Riga, Riga, Latvia

Definition

Sustainable happiness is a wide concept. It characterizes conditions under which happiness, understood broadly as a mental state, attitude, and functioning, is individually and collectively secured or enhanced in the long run while preserving the natural and social environment. Thus, happiness is sustainable in two ways. First of all, it is sustainable *qua* happiness, namely, it characterizes situations where the individual or community is flourishing in the long term. Put differently, happiness achievement in the short run does not impair its realization in the future. Second, such happiness spares social and natural resources, namely, it minimally guarantees an equivalent access to these resources for the future generations. In other words, happiness is at least compatible, at best conducive, to sustainability understood as the preservation of economic, social, and environmental resources necessary for the satisfaction of future generations. The assumption of sustainable happiness is

that these two dimensions are intimately correlated.

Introduction

For the last two decades, the interest in happiness has been swelling in industrialized countries. The reasons are multiple. On the one hand, it expresses deep concerns for quality of life, especially as reported by the individuals themselves, in a period of limited resources. Since the mid-1970s, growth in advanced economies has been stagnating, well under its level during the 1950s to early 1970s period. The impact of limited resources and economic instability became prominent after the 2008 crisis. At this point of time, individuals, organizations, communities, and governments have started to investigate how to maintain well-being in a languishing economy.

The idea spread that human beings cannot rely on indefinite, high-paced expansion of goods and services for securing their quality of life. Deeper worries also build up about the distinction between needs and wants, between what is necessary and superfluous for leading, if not a good but at least, a contented life. The core argument has been that market and capitalist economies have overall performed very well for satisfying needs, but at the price of inflating waste, nurturing superfluous preferences, and so forth.

This stream of concerns has generated a tremendous number of studies, articles and books, official reports, and so forth. The academic research on happiness has developed throughout various fields such as psychology, economics, sociology, philosophy, or public policy, involving prominent authors such as Ed Diener, Richard E. Easterlin, Robert Frank, Bruno Frey, Daniel Gilbert, John F. Helliwell, Daniel Kahneman, Richard Layard, Martin Seligman, or Ruut Veenhoven. Governments and international organizations have investigated different approaches of well-being measurement, e.g., the Commission on the Measurement of Economic Performance and Social Progress, or Stiglitz-Sen-Fitoussi Commission, in France, OECD with its *Guidelines on Measuring Subjective Well-being* published in 2013. The United Kingdom and

Japan conducted their own work. The annual *World Happiness Report* edited by John F. Helliwell, Richard Layard, and Jeffrey Sachs illustrates the popularity of the topic.

On the other hand, the period that opens with the 1990s has witnessed soaring concerns about a second set of pressing issues: climate change and sustainability. The United Nations Conference on Environment and Development in Rio (1992) and the ensuing Conferences of the Parties (COP) under the United Nations Framework Convention on Climate Change (UNFCCC) constitute prominent examples of the rise. The economic model based on indefinite growth, criticized for its inability to generate lasting, i.e., sustainable, satisfaction, was equally accused of being unsustainable, wasting natural resources, and altering the climate dangerously.

This context characterized by growing concerns about quality of life and environmental sustainability explains the emergence of the, still developing, field of sustainable happiness. More than a unified domain, it refers to a concept that is in use among a porous network of activists, researchers, and policy makers for describing diverse approaches.

As a first approximation, sustainable happiness can be defined as “the pursuit of happiness that does not exploit other people, the environment, or future generations” (O’Brien 2008). This definition contains two facets: first, happiness that perpetuates itself (or its possibility), and second, happiness that preserves the natural and social environment. This links concerns for sustainability expressed by the Brundtland Commission (1983–1987), the United Nations Conference on Environment and Development in Rio (1992), and the Agenda 21 to worries about well-being initiated by Richard A. Easterlin works (1974).

Sustainable Happiness-es

On the one hand, happiness is sustainable *per se*, viz. as happiness. Happiness is a concept that allows different interpretations and covers a large variety of dimensions. The academic

literature identifies four main conceptions: hedonia, mood theory, life satisfaction, and eudaimonia.

Hedonia boils down to maximizing pleasant experiences and minimizing unpleasant ones. It is constituted by the sum of mental states, i.e., a matter of positive and negative effects. A happy life describes a life where individuals *feel good*. Etymologically, it originates from *hēdonē*, which in old Greek means “pleasure.” Articulated by Jeremy Bentham, modern hedonism deeply influenced early utilitarianism and economics (e.g., Stanley Jevons, Francis Edgeworth). Coupled with life satisfaction, this conception is the most popular among psychologists.

The second formulation is the mood theory as advanced by Daniel Haybron (2008) which distinguishes central emotional states from peripheral ones. The former, which constitute the mood, are more enduring than the latter, which characterize hedonia. They last longer than fleeting experiences of pleasures and pains. They are more robust and, moreover, more intimately connected to one’s sense of identity. In sum, they are dispositions capturing the psychological inclination of individuals, i.e., their propensity to undergo rather positive or negative effects, as well as some deep traits, for instance, openness, conscientiousness, extraversion, agreeableness, and neuroticism.

The third conception is life satisfaction. Contrary to the former two, which are based on mental states, life satisfaction is an appraisal of one’s life. Social scientists use self-assessments for evaluating it. They survey people about how happy or satisfied they feel with their life in general (life satisfaction) or with some dimensions such as job, marital, health, and relationship (domain satisfaction). It is therefore a construct. When respondents are asked how satisfied they are with their whole life or parts of it, they are requested to undertake a cognitive reconstruction. The result takes the form of a numerical assessment on a X-point scale (X usually varying from 3 to 10).

Combined with hedonia, life (or domain) satisfaction is the dominant conception among psychologists and social scientists such as Ed Diener. It is also the most commonly used for large-scale

surveys. Although Richard Layard (2005) defines happiness as “feeling good,” therefore as hedonic, his reliance on self-assessment suggests that his conception is closer to life satisfaction. Furthermore, satisfaction is usually aggregated with positive and negative effects (hedonic dimension) for creating subjective well-being, which is a composite indicator.

The last conception is eudaimonia (from the old Greek, *eu* – , “good,” “true,” and – *daimon*, “spirit”). It originates from Aristotle’s *Nicomachean Ethics* (2009), where eudaimonia is identified with the realization of higher faculties and virtues. It has been particularly influential on virtue ethics, which judges actions and states of the world insofar as they are in accordance with underlying moral virtues (e.g., generosity, courage, and honesty). While the other three conceptions are subjective, eudaimonia was initially (and is still often) interpreted as an “objective” approach, namely, that an outside observer could evaluate one’s happiness by using a list of objective achievements.

Throughout time, eudaimonia has lost some of its “objective” character. It gradually started to be identified with self-accomplishment while some of its focus on higher faculties and virtues faded away. It still relates to the realization by an individual of an ideal good life or some individual potentialities. However, the stress is less on the realization of absolute virtues and more on flourishing based on one’s specific skills and values or more generally adequate functioning. Due to its connection with the good life, the eudaimonic conception has been particularly prevalent in philosophy (e.g., Julia Annas, Richard Kraut), while less popular in psychology despite some prominent representatives such as Martin Seligman’s authentic happiness (Seligman 2002), Alan Waterman, or the self-determination theory (Ryan and Deci 2017).

In that context, sustainable happiness, *qua* happiness that perpetuates itself (or its possibility), seems *a priori* incompatible with pure hedonic enjoyment, since pleasures (and pains) constitute fleeting experience, and it is very unlikely that individuals can maintain a condition of unfading hedonia. To the contrary, moods, satisfaction, and

eudaimonia possess more this much persisting characteristic.

Sustainable happiness stands at odds with behaviors that do not bring enduring positive mental states (moods), satisfaction, or functioning. Its qualities should be consistent with a robust experience that extends through time, while allowing variations for obvious reasons (no life can only be loaded with satisfaction, positive psychological dispositions, or constant flourishing).

In that sense, the pursuit of immediate gratification, frequently associated with hedonia, might turn out to be incompatible with sustainable happiness because it might divert individuals from different, but more enduring, positive experience (e.g., in relation to the development of one’s capacities). For instance, sustainable happiness could be understood as objecting to the quest for materialistic values, since such values are correlated with poor mental health in psychological research (Kasser 2002).

Despite these limits, hedonia remains crucial for sustainable happiness since it is dubious that a life packed with constant or recurrent, intense, pain is worth living. Whereas hedonia cannot be *the* core conception of sustainable happiness, it is still key for its accomplishment. In sum, if sustainable happiness cannot be reduced to hedonic experience, the absence of overwhelming negative mental states appears to be a prerequisite.

Sustainable Happiness As Sustainability

On the other hand, it refers to happiness respectful of people and the nature. This dimension articulates a critique of an economic model based on mass production with little regard for the preservation of natural resources and human dignity. Conspicuous consumption, in which large amounts of resources are wasted in the sake of relative standing and status seeking, epitomizes unsustainability from both happiness and social-environmental sides.

The central claim is that any step for improving individuals’ mental state, attitude, and functioning in the present should take seriously the overall impact on the Earth and other human beings. In

short, well-being cannot be conceived as an egoistic quest and should include wider considerations. Even at the individual level, an eye should always be kept on the quality of life of the immediate and more distant communities and generations.

Sustainable happiness can be understood in a broader context characterized not only by global issues (e.g., poverty and climate change), but also by a growing discontent since the Great Recession toward a specific economic model. Since the late 2000s, an increasing number of people have started to challenge the view of development funded on mass production and consumption with severe pollution, resource depletion, and exploitation.

Sustainable happiness tackles the very idea that quality of life directly depends on constant material expansion. The core assumption is that it is possible to combine sustainability in a large sense (including economic, social, and environmental aspects) with the maintenance, or even enhancement, of well-being. This postulate contradicts conceptions of development that strictly tie improved living standards with rising affluence.

In addition, sustainable happiness is grounded on the view that well-being does not result from an individual enterprise led in isolation from a community and global issues. It is a collective endeavor, which requires people to use resources with parsimony, cooperate, and avoid producing externalities (i.e., costs imposed on others in terms of resource depletion, pollution, exploitation, abuses, and so forth). It deepens the contrast with economic growth as it has presumably been undertaken from the onset of industrialization in the nineteenth century, with the drastic acceleration since the afterwar period. To that respect, sustainable happiness claims to figure or participate to a necessary paradigmatic or civilizational shift.

The Easterlin Paradox

Therefore, sustainable happiness merges sustainable development as coined by the Brundtland Commission (“development that meets the needs of the present without compromising the ability of future generations to meet their own needs”

[World Commission on Environment and Development 1987]) with the happiness studies that followed the Easterlin paradox.

The Easterlin (or happiness) paradox has been proposed by the economist and historian Richard A. Easterlin (1974). The paradox tackles the correlation between economic growth (captured by the Gross Domestic Product) and happiness (approximated by satisfaction). It posits that, although wealth and satisfaction are strongly correlated within countries and moderately correlated in comparisons between countries, longitudinal, national, studies (e.g., Japan and the USA) do not show any significant improvements of happiness over time despite tremendous economic growth.

The paradox has generated a fair amount of methodological, economic, social, and political controversies (Deaton 2013), some being rather technical. In substance, the main objections are that happiness, even under the form of satisfaction, is not a reliable indicator of people’s quality of life (individual self-assessments would be “tainted” in one way or another), that a correlation exists between happiness (or quality of life) and material affluence, and, finally, that even if such correlation is absent nothing can, or should, be done about it. In sum, the normative implications would be thin or inexistent.

Nonetheless, the paradox had supported skepticism toward capitalist and market economies. It has been interpreted as the proof that “money doesn’t or can’t buy happiness.” The direct consequence would be that citizens and institutions should change the scope of their efforts, pursuing other objectives than becoming wealthier. Beyond the debates on society models, the paradox has nurtured more targeted, concrete approaches, such as Robert Frank’s proposition to implement an incremental tax on consumption (Frank 1999). The assumption is that if economic growth fails to deliver happiness, at least when considering industrialized countries through time, it is due to a sizable part of the wealth being used for conspicuous spending, positional goods, and so forth. Individuals in developed nations would waste money trying to assert their status by unnecessary expenditures that do not bring lasting satisfaction.

Along this paradox, sustainable happiness aims at contributing to societies where well-

being can be secured without jeopardizing such security for other people and future generations. For achieving this goal, a large diversity of instruments and policies can be mobilized. Although the field is still in its infancy, there are already initiatives for rethinking urban planning, educational curricula, methods of governance, quality of life indicators, waste management (e.g., with upcycling), and so forth. Individual autonomy and endorsement of a sustainable approach are especially underlined, which rules out too strict constraints and top-down solutions despite the fact that sustainable happiness clearly articulates individual and collective dimensions.

Various initiatives, not always explicitly associated with sustainable happiness, express the same concerns for sustainable development coupled with well-being (approximated by concepts such as well-being, happiness, and so on). One is the *Happy Planet Index* proposed by the New Economics Foundation. It is a composite indicator combining measurements of life satisfaction, life expectancy, and equality in relation to the ecological footprint of (usually) a country. Another instance is Bhutan's *Gross National Happiness Index*. It is also a composite indicator that monitors nine domains (living standards, health, education, good governance, ecological diversity and resilience, time use, psychological well-being, cultural diversity and resilience, and community vitality) through encompassing surveys of 148 questions (Centre for Bhutan Studies and GNH Research 2016).

Along with other concepts and initiatives, sustainable happiness is still in the making. Thus, its potential implications and impacts on the socioeconomic organization of our societies are not obvious yet. Many of these outcomes may unfold in the year to come depending on the concrete projects that will be led. Nonetheless, it could be objected against the whole demarche that by focusing on voluntary reforms at the individual and community level, it fails to measure up to the global issues of climate change or pollution. Due to the magnitude and seriousness, it might be argued that the only workable solutions are constituted by public intervention under the form of international agreements, state regulation, and coercion. However, sustainable happiness and

more “command and control” approaches are not mutually exclusive. They could even be designed in a self-reinforcing manner.

Summary

Sustainable happiness captures the two-pronged objective of enduring well-being in the respect of the social and natural environment. The first objective is to promote forms of happiness that could be sustained in the long run. While overwhelmingly negative hedonic experience can be an obstacle, the enduring forms of happiness relate to moods, satisfaction, and individual flourishing. The second objective is to promote happiness in a manner that is respectful of the future generations and of the environment. Therefore, sustainable happiness offers a response of global challenges such as climate change, pollution, economic exploitation, and quality of life. It is part of a more ambitious project, which is of reforming the economic model inherited from industrialization. The aim is to revamp institutions and governance, and educate citizens, so they understand more clearly what lasting well-being entails in a world of limited resources. Despite its intention, sustainable happiness remains in the making and could be criticized as not fully measuring up to the seriousness and extent of the global issues it tackles.

Definition

The concept of sustainable innovation is related to a new understanding of the innovation process, which pursues to include the three main areas of sustainability (environmental, social and economic) from Research and Development (R&D) to commercialization.

The notion of sustainability is introduced by Brundtland et al. (1987), referring to sustainable development. In this approach “sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland et al. 1987, p. 41). This viewpoint is considered in different approaches in the 1990s. Elkington (1994, 1997) proposed the bottom three approaches and the People, Planet, Profit: 3P approach. The People dimension is to encompass the social issue, the Planet dimension incorporates the environmental component and the Profit dimension integrates the economic system.

For instance, Ehrenfeld (2008, p. 1) defines “...sustainability is the possibility that human and other life will flourish on the planet forever”. Thus, fostering sustainability requires the development of new products or processes that integrate these 3 dimensions: 3P approach. In other words, sustainability involves innovation.

Regarding sustainable innovation, this differs from regular innovation, since it pursues to reduce the negative impact on environmental, social and economic dimensions (Charter and Tischner 2001). It should be noted that it is possible to find different definitions of innovation. At the moment we will limit ourselves to García and Calantone's definition: “innovation is an iterative process triggered by a new market and/or a new service opportunity for a technology-based invention that leads to developmental tasks, production and marketing that seeks the commercial success of the invention” (García and Calantone 2002, p. 112).

Therefore, following Cilo et al. (2019, p. 1014) and Tello and Yoon (2008, p. 165) sustainable innovation is defined as “the development of new products, processes, services and technologies that contribute to the development

and well-being of human needs and institutions while respecting natural resources and regeneration capacities”. Also, for Bos-Brouwers (2010, p. 422) sustainable innovation is defined as “innovations in which the renewal or improvement of products, services, technological or organizational processes not only delivers an improved economic performance, but also an enhanced environmental and social performance, both in the short and long term have the capacity to generate positive social and environmental impacts”.

Introduction

Sustainable innovation is crucial to promote sustainability in the company. Innovations that contribute to sustainability are, for example, called eco-innovations, green innovations, sustainability-oriented innovations or sustainable innovation (Klewitz and Hansen 2014).

Considering the traditional view of Oslo Manuel (OECD/Eurostat 2005, p. 16) “it covers four types of innovations: product, process, organisational and marketing”. In this viewpoint, innovation can take the different types to improving sustainability: the introduction of a new product using different raw materials (product innovation), changes in production and delivery methods (process innovation) (Steiner 2008), changes in business practices, in workplace organisation or in the firm’s external relations (organisational innovation), changes in product design and packaging, in product promotion and placement, and in methods for pricing goods and services (marketing innovation) that reduce the environmental impact.

Sustainability (Elkington 1997), sustainable development (Brundtland et al. 1987) and innovation are controversial and controversial concepts. Consequently, a clear or uniform definition of “sustainable innovation” has not yet been published. The literature is full of publications that take into account only the environmental dimension of innovation. Various terms such as “green innovation” or “eco-innovation” are often used in these documents (e.g. Carrillo-Hermosilla

et al. 2010; De Marchi 2012; Hellström 2007; Horbach 2008; Kesidou and Demirel 2012; Schiederig et al. 2012).

Sustainable innovation reflects a broad range of issues as important drivers for implementing innovation related to sustainability (Bacinello et al. 2020).

From the company’s point of view, it is fundamental to consider the environmental orientation of innovation due to its economic impact, referring to eco-innovation impact in terms of the product’s life cycle or other relevant dimensions (OECD 2009). However, this particular perspective on sustainable innovation ignores the social dimensions of the concepts of innovation and sustainability.

Indeed, the concept of sustainable innovation presupposes that “the result of the innovation process somehow shows sustainability” (Achterkamp and Vos 2006, p. 526) or that the innovation contributes “to sustainable development from an economic, ecological and social point of view” (Steiner 2008, p. 596), which is reflected in “sustainability-oriented innovation” or “sustainable innovation” and that include other aspects besides environmental concerns (Klewitz and Hansen 2014).

Sustainability-oriented innovation has been defined as “the commercial introduction of a new (or improved) product (service), product service system or clean service based on traceable comparative analysis (qualitative or quantitative), leading to environmental and/or social benefits during the physical life cycle of the previous version (‘cradle to grave’)” (Hansen and Große-Dunkirk 2013, pp. 2407–2408).

Thus, according Bacinello et al. (2020, p. 752) “sustainable innovation is related to innovations that incorporate economic, social, and environmental issues as the engine of competitive advantage, adding positive net value to the company (Anser et al. 2017; Gallego-Álvarez et al. 2011)”. It is about introducing new or improved products, processes, organisational and marketing methods or systems which reflect the social, environmental and economic dimensions of sustainability (Halila and Hörte 2006).

Key Issues

The ideas of sustainable development arise from the discussion on “five principles based on fairness: futurity – intergenerational fairness; social justice – fairness within generations; cross-border responsibility – geographical fairness; procedural fairness: persons treated openly and fairly; and interracial fairness – the importance of biodiversity” (Haughton 1999; Hopwood et al. 2005).

Thus, sustainability emerges, firstly, focused on the concept of diversity (Rocha et al. 2007) and considering the three goals: “achieving economic goals (profits), but also to the need to achieve environmental and social goals (or essence) at the same time in business” (Harding 2006, p. 232).

Gibson (2006), Rocha et al. (2007) and Stevens (2005), for example, consider other dimensions for sustainable development as: “social and ecological integrity; option; equity; efficiency and performance reduction; democracy and civilization; caution and adaptation; immediate and long-term integration”. Figure 1 summarises the dimensions of sustainability from Stevens’ (2005) approach.

Sustainable innovation involves fewer environmental impacts and produces a better image in social terms and can thus lead to greater profits. In this sense, business models must face these challenges in production, branding, marketing and sales and develop a business culture that integrates this change. According to the Ottosson (2009) model, innovation is at the core to lead to good service, sustainable profit and a better world (Fig. 2).

In addition to new business models, sustainable incremental innovation such as changing staff behaviour in relation to energy use, the process of encouraging new and more sustainable behaviour can lead to significant internal changes with positive sustainability outcomes.

Thus, sustainable innovation has become a challenge for companies and there are several reasons to bet on this new reality: changes in consumer perceptions and behaviour; rising commodity prices; less polluting technologies that are becoming cheaper; shareholders who identify good sustainability performance with good management.

Sustainable innovation also requires cooperation: cooperation between individuals, departments and organisations. Cooperation to access resources, to produce a wider range of initiatives, to share costs and risks, and to access finance.

Future Directions

In effect the adoption of sustainable innovation practices produce positive results in business performance, namely: “integration with local communities and other stakeholders to generate social and environmental benefits; mechanisms of interaction with stakeholders; practices to reduce emissions in the supply chain; Product-Service System that seeks to create alternatives for product replacement by services; sustainable practices to ensure stakeholders’ well-being; and production systems and selected suppliers to provide environmental and social benefits” (Kneipp et al. 2019, p. 109).

Sustainable Innovation,

Fig. 1 Dimensions of Sustainable Development (Stevens 2005)

Sustainable Innovation,
Fig. 2 Aims of Innovation
 (Ottosson 2009)

Sustainable development requires innovative behaviour and innovation by all (Boons and Lüdeke-Freund 2013; Matos & Silvestre, 2013). Clean technologies and those that reduce carbon use will be key to mitigating climate change (Wennersten et al., 2015).

The concerns with sustainability and the studies on the theme of sustainable innovation have highlighted the importance of the following aspects in the promotion of sustainable innovation:

1. Systemic cooperation (Chesbrough and Rosenbloom 2002; Soosay and Hyland 2015) warning of the need to strengthen “the collaborative process, including the sharing of knowledge, benefits, challenges and partnerships” (Mbeguéré et al. 2014, p. 59).
2. The negative externalities of innovation and the clear definition of responsible or sustainable innovation (Koops et al. 2015) seeking to investigate how firms and entrepreneurs can jointly develop and build capacity to promote these sustainable innovations.
3. Difficulties in defining the concept of sustainability and the multidisciplinary nature of sustainable innovation leads to different approaches to conceptualising and operationalising sustainable innovation constructs (Cillo et al. 2019).
4. The relationship between knowledge management and sustainable organizational innovation (Abbas et al. 2020), the connection to

open innovation 4.0 as driver of sustainable innovation ecosystems (Costa and Matias 2020).

5. Public policies and government subsidies to promote sustainable innovation in university-industry collaboration as strategic of this ecosystem (Song et al. 2022).

According to Silvestre and Țîrcă (2019), as future research we point to:

1. Studying how SD innovations differ in the vast literature on the three themes: technology, management and policy and how different types of innovation fit into the traditional, green, social and sustainable strand. Such research will help a more detailed understanding of which types of innovations are most relevant and can actually make the greatest contribution to sustainability.
2. Developing studies on the different types of innovations: traditional, green, social, sustainable, from different perspectives: management technological and policy and how they influence the four uncertainties of innovation (i.e. technological, commercial, organisational and social – TCOS). This study will contribute, in practical terms to reduce or eliminate uncertainties, given the type and approach to specific innovation in sustainable development.
3. Research on how managers can maximise sustainability trajectories and the best management

approaches and perspectives that can be applied in all cases.

4. Developing more radical approaches to sustainability and innovation. Intensify research to identify and assess the barriers and factors underlying new sustainability perspectives, such as Sustainable Innovation 4.0 and its “triple bottom line” approach to refining and empirical testing.

In another perspective, for instance, for Griswold et al. (2018) the future of sustainability passes through the involvement of higher education students, with curricula that include these themes in an incisive and articulated manner.

In sum, the new topics on sustainable innovation should cover: (1) new cooperation models for sustainable innovation; (2) how companies are transforming their innovation; (3) how to structure sustainable innovation to combat business resilience; (4) how millennials are shaping their future innovation; and (5) how to build innovation ecosystems.

Synonyms

Conscious Investment; Environmental Investment; Ethical Investment; Green Investment; Impact Investment; Responsible Investment; Social Investment; Socially Responsible Investment (SRI)

Definition

Sustainable Investing (SI) is a responsible way of investing. It is defined as an approach that takes into account environmental, social, and governance (ESG) factors in investment portfolio selection and management (GSIA 2018).

SI acknowledges the importance of making a financial return but does not forsake ethical, social, and environmental responsibilities in pursuit of high returns. In fact, the same diligence that

is accorded to measure financial returns is accorded to social and environmental returns with SI.

Though often used interchangeably, there is some difference between SI and Socially Responsible Investment (SRI). SI is objective and proactive, in that, it looks at social, ethical, or environmental issues as challenges or opportunities that can be remedied while delivering returns (Cunha et al. 2019). Some examples are waste management, telecommunications, renewable energy, etc. SRI, on the other hand, is much more defensive and reactive, in that, it avoids investing in ethical, social, and/or environmental laggards. SRIs are subjective; in other words, what is right and therefore acceptable, and what is wrong and therefore unacceptable, is relative.

History

Sustainable investing is not new (Schueth 2003). It has been around in different forms since religion happened. SI or responsible investment is said to have been practiced when religious institutions avoided certain forms of “sin” businesses such as slave trading, gambling, alcohol, pornography, etc. Religious beliefs drove the investments toward more socially and morally acceptable trades. This form of investing is where funds are “screened,” i.e., funds are invested in morally and socially good business, or funds are withheld from immoral and socially irresponsible businesses (Renneboog et al. 2008). In the modern version of SI, environmental issues and norms are also included while screening.

The first such fund is attributed to the Pax World Balanced Fund, a mutual fund established in 1971. This fund allowed investors to avoid investing in companies profiteering from the Vietnam war (Townsend 2017). There were several catalysts that helped accelerate the growth of responsible funds, such as boycotting of the South African companies in the 1980s during the apartheid regime (Kumar et al. 2002), the Exxon Valdez spill in 1989 (Leahy 2019) which brought to fore the environmental aspect of irresponsible investing, among others. The 1980s also saw the

inception of EIRIS foundation in England which was one of the first to provide research in the area of ethical and responsible investing (EIRIS Foundation 2020).

Since then, the need to direct finance more responsibly has become more mainstream. For instance, the Kyoto Protocol of 1997 saw the world officially agreeing to reduce carbon emissions to prevent global warming (United Nations 1997). This was followed by the Global Compact which is an effort to protect human and labor rights, prevent corruption, and protect the environment (United Nations 2000), and Global Reporting Initiative (GRI) which creates more transparency in terms of a company's ESG behavior. The UN Principles of Responsible Investing (UNPRI) is another step in this direction and aims to also educate investors in the context of SI.

In 2015, the 2030 Agenda for Sustainable Development was adopted by all UN member states with the aim of combating poverty while addressing climate change (United Nations 2015). The 17 Sustainable Development Goals (SDGs) established at the heart of this agenda aim to tackle economic, environmental, and social challenges facing humanity. SI now therefore has become imperative to successfully achieve the SDGs. Today SI forms a core part of most companies' CSR policies.

Methods

SI incorporates different methods to identify requisite investment opportunities. It is more active, in that it looks for ESG challenges which are then "fixed" while generating a financial return (Eccles and Klimenko 2019). Some examples here are clean technology, community development, health services, alternative energy, etc.

SI can also be a strategy which includes share/stakeholder activism wherein share/stakeholders actively engage with the companies to bring about a change, e.g., stakeholders demanding fairer supply chains, or shareholders forcing companies to uphold labor rights or stamping out corruption or seeking more transparency in terms of environmental issues, amongst others (Eccles and

Klimenko 2019). SI also pioneers "green" innovation by providing (seed) capital to relevant ESG projects.

SRI is on the passive side and uses, in large parts, the screening method. There are different types of screens used, often in combination and also very often used by SIs. As detailed by Eccles and Klimenko (2019), these are,

- Positive screening – this is an affirmative screen, in that, here the investment portfolio includes the so called "good" companies. Here selection of investments is made on the basis of which companies suit social, environmental, or ethical criteria best. Very often, a triple-bottom-line approach is applied to make the selection. For example, an investor might invest only in companies with proven track record not only in financial terms but also in protecting the environment.
- Negative screening – here investment portfolio excludes the so-called "bad" companies. Those companies which fall short of the necessary social, environmental, or ethical criteria are left out of the investment portfolio. For instance, an investor refuses to invest in companies manufacturing guns or military equipment.
- Norms-based screening – this combines both positive and negative screening. Here companies are chosen based on specific norms. For example, companies that have signed on to the global compact are included in the investment portfolio and those that have not done so are excluded from the portfolio.
- Best-in-class screening – here, as the name suggests, those companies that are best in terms of a certain set of social, environmental, and/or ethical criteria are included in the investment portfolio.

Current Developments

On the product side, between 2016 and 2018, the SI has grown 34% worldwide reaching US\$30.7 trillion (GSIA 2018). According to the same report, SI makes up nearly half of total

professionally managed funds in Europe and about 26% in the USA.

On the market side, in 2018, 35 stock exchanges from 30 countries offered sustainability indices (Cunha et al. 2019) which represent a growing and liquid market. Such developments stimulate SI considerably. Investors routinely use such indices for benchmarking and investing (European Union High-Level Expert Group on Sustainable Finance 2018).

UN Global Compact is currently making a case to issue SDG bonds which will further facilitate trade in the SI market (Global Compact 2019).

It is apparent that incorporating ESG strategies into investment decisions is now not a random occurrence but more of a standard due diligence. For example, according to Eccles and Klimenko (2019), sustainable and impact investment has more than tripled since December 2016, with \$17 billion in AUM at UBS Asset Management. Moreover, in 2019 alone, ESG funds pulled in US\$ 20 billion which is four times the similar investments in 2018 (Iacurci 2020).

SI and CSR

The idea that being socially responsible actually is good for the long-term sustainability is not a new one. A journalist who is renowned to have started making the “Best Companies” list with Robert Levering in the early 1970s, Milton Moskowitz (1973) wrote “I do harbor the suspicion that a socially insensitive management will eventually make enough mistakes to play havoc with the bottom line.” He believed that a company that had a good CSR policy, which looked after the employees, treated them fairly, was transparent in its dealings, and generally a good corporate citizen made a good investment candidate.

Idiosyncratic risks of companies can, in theory, be diversified by constructing a balanced portfolio. However, companies which do not pay attention to ESG factors and then are eventually penalized in one way or another will find it difficult to sustain themselves in the long run. Such companies risk losing their investments and also face possible ruin. Such companies could get

caught out by legal action like in the case of diesel motor scandal (Volkswagen), or be stuck with stranded assets like in the case of fossil fuel companies, or face customer boycotts as in the case of fur and blood diamonds.

In today’s world, with all the signs of global warming being present and pressing and with social inequality increasing, the growth of the SI shows that there is a growing acknowledgment that incorporating ESG factors in investment decisions could lower risks and improve financial performance over time. In other words, researching and analyzing ESG factors could help create an efficient portfolio.

Cunha et al. (2019) show that though SI performance around the world is still heterogeneous, and investors incorporating SI practices in their investments are likely to generate better risk-adjusted returns.

More and more regulators, governments, and also financial decision makers are seeking wider reaching sustainable investment solutions. This is evidenced in the fact that in 2018, 60% more assets, globally, are managed with SI strategy of ESG integration as compared to 2016 (GSIA 2018).

More and more companies are signing up to the UNPRI and are actively engaging with the UN Sustainable Development Goals (SDGs). Such companies are, in many cases, the right candidates for SI.

Sound CSR policies of a company incorporate ESG factors in their processes and decision-making which in turn assure the company’s long-term (financial) sustainability. More and more companies and their stakeholders recognize this, and this in turn increases the portfolio universe of sustainable investments. SI is no longer a passing thought but is a strong movement, driven by committed stakeholders on all levels with serious sums of funding being directed toward responsible companies.

[CSR leadership](#); [Global leadership](#); [Good leadership](#); [Leadership](#); [Responsible leadership](#); [Sustainability leadership](#)

Definition/Description

There are numerous definitions of sustainable leadership. These differ concerning the various concepts of “leadership” and “sustainability.” Despite the different perspectives on leadership, a common idea they all share is that leadership involves influencing other people’s behavior, beliefs, and feelings. The critical characteristic of sustainable leadership is its sustainable development orientation. It involves taking on the responsibility to contribute to social, ecological, and environmental progress within the organization and beyond organizational boundaries.

Sustainable leaders incorporate various stakeholders inside and outside the organization to inspire and support action towards a better world. Thus, sustainable leadership can be defined

as influencing the behavior, beliefs, and feelings of other people (inside and outside the organization) to contribute to sustainable development progress. Its three significant characteristics are systemic perspective, relationship building, and sustainable development orientation. In this sense, the construct of sustainable leadership is intertwined with theoretical and practical developments in corporate social responsibility, business ethics, sustainable development, and leadership. These concepts have in common that short-termism, the sole focus on profit maximization, and shareholder-only orientation no longer meet the challenges of an increasingly complex environment and interconnected world.

Introduction

The dynamics and complexities of daily business and different assumptions and beliefs about what is right and wrong make leading in a globalized world increasingly difficult. This pressure is increased by economic, social, and ecological challenges raising the demand for companies to contribute to a sustainable future. Traditional leadership behavior (such as command and control, authority, and domination, asserting influence through hierarchical structures) relies on an outdated assumption of treating people. In addition, new technologies, educational systems, and worldviews have changed how people relate to each other, collaborate to deal with global challenges and create meaning. Therefore, traditional leadership concepts appear outdated in the knowledge society and are not suitable for the sustainability challenges business and societies face. This leads to the need for a changing leadership paradigm.

Senge et al. (2004) propose that leadership can be defined as the ability of human society to create its future. This definition shifts the view of associating leadership with a group or society rather than one single person. Companies today are faced with the task of managing the simultaneous consideration of economic, social, and ecological system views. This complexity leads to a substantial shift towards the principle of

sustainability, which aims to integrate these three areas. Thus, they strive to balance social, environmental, and economic values and progress within their organization but also beyond their organization.

A new kind of leadership is emerging – one that does not depend on extraordinary hero leaders but a form of leadership applied by groups and communities (Senge et al. 2004). This raises the question of what leadership concepts and behavior for sustainable development would look like.

Three Core Characteristics of Sustainable Leadership

The essence of sustainable leadership revolves around the future in which the conditions in society and economy are different from today. To manage the growing complexity and interconnectedness of social, ecological, and economic topics, leaders require a long-term focus on their companies' effects on societies and the environment.

Therefore, sustainable leaders need three core characteristics to manage this complexity.

1. Systemic Perspective

Sustainable leadership can be understood as an answer to the challenges of the increasing complexity of systems. With this, sustainable behavior is a holistic approach that incorporates social, ecological, and economic aspects. Activities and decisions cannot be viewed in isolation but have intended, unintended, recognizable, unrecognizable effects on other areas (Ferdig 2007).

2. Sustainable Development Orientation

The orientation towards sustainable development is a global challenge that leads to a complex situation in which leaders must make well-considered decisions. Therefore, sustainable leaders address economic, social, and ecological issues with a long-term view while being aware that long-term success cannot be achieved without short-term delivery (Hind et al. 2009).

3. Relationship Building/Mutual Meaning-Making

Sustainable leaders understand the value of people across cultures, belief systems, and worldviews by recognizing, interpreting, and reacting appropriately to people, organizations, and other stakeholders. They facilitate relational processes among teams and communities and take on the responsibility for the quality of these relationships. For them, waving a net of inclusion of stakeholders is crucial to achieving long-term success for everybody involved.

- Passionately and humbly strive to leave behind dignified, lasting legacies for present and future generations, thus creating real purpose and meaning.
- Pursue a shared agenda that serves the common good.
- Consistently act ethically and with integrity.
- Demonstrate genuine, authentic care, and compassion.
- Enable and empower people.
- Are unconditionally committed to being the best leader possible.
- Serve as an exemplary role model.

Behavior

These characteristics of sustainable leadership are manifested in the behavior within the leader-follower construct. The following behaviors can be associated but are not limited to a sustainable leader.

Sustainable leaders (Veldsman 2018)

- Visualize and mobilize people for an inspiring, shared future, a dream, turning stakeholders into committed followers.

Leadership makes a difference in the presence and future of teams, organizations, communities, and society, for better or for worse. Based on the above, leadership capital is a critical investment in the future of organizations, communities, and societies at the top front. In addition, it has a significant impact on the “bottom line.”

The sustainability challenges of the world and aspirations for a more sustainable future calls for certain types of leadership and manifest themselves in the following model (Fig. 1):

In the Cambridge sustainability leadership model, context describes the conditions or

Sustainable Leadership, Fig. 1 Cambridge sustainability leadership model (Visser and Courtice 2011)

environment in which leaders operate that directly or indirectly affect their institutions and decision-making. This context is broadly divided into external factors – e.g., ecological, economic, political, cultural, and community – which leaders may have less influence over and internal factors – e.g., the organizational culture, governance structure, or role of leadership – which they have more influence over.

Ultimately, it highlights how the new characteristics of sustainable leaders can be implemented in the proper context. Based on this, leadership and leadership development is an essential investment in the future and have a significant impact on our society. Therefore, the race for the future will be won by organizations that consciously build sustainable leadership.

Future Directions

In light of the grand social challenges of our time, we currently witness a reconceptualization of the leadership construct. Leadership will become a wider, organizational boundaries overarching concept to deliver on sustainable development progress. Future research will deal with the effects of leadership behavior not only on the organizational performance but moreover on the societal progress.

Summary

We witness the emergence of a new kind of leadership. Sustainable leadership aims to address the demand of an increasingly complex and rapidly changing world, which traditional leadership behavior cannot meet. Sustainable leadership means empowering people in their behavior, beliefs, and feelings inside and outside of an organization through a systematic perspective, relationship building, and a sustainable development orientation. As role models, sustainable leaders treat people with compassion, have a holistic view, and create real purpose and meaning.

Sustainable Lighting Design

Ioannis Φ. Panagiotopoulos
University of the Aegean, Chios, Greece

Synonyms

[Environmentally Responsible Lighting Design \(ERLD\)](#); [SLD](#)

Definition

Sustainable Lighting Design (SLD) has been proposed by Panagiotopoulos (2019) as this kind of Lighting Design (LD) that consisting part of a Corporate Social Responsibility (CSR) program examines economic, social, and environmental issues. In comparison with Environmentally

Responsible Lighting Design (ERLD) which focuses on environment analyzing the interaction between LD and environment, SLD further considers societal and economic parameters, and thus, it fully covers all aspects of sustainability. SLD as term supports the theoretical background for the consideration of the element of light as a sustainable parameter for the design of corporate buildings and workplaces as part of a holistic CSR design for energy usage optimization, environmental footprint minimization, health and safety, and productivity enhancement.

Introduction

Big international companies occupy buildings for their production activities and their administration like in the case of their headquarters. Buildings in general emit 50% of CO₂ emissions in developed countries because they have increased needs for heating, cooling, lighting, ventilation, and the operation of any electric, electronic, and mechanical equipment inside them. Especially lighting is an element that affects other parameters like heating and cooling, and it relates to the consumption of electricity and consequently with the total energy needs of a building (Strong and Burrows 2017). The multi-level effects of lighting in energy and gas emissions, human mood, health, etc. indicate that lighting design (LD) is a significant element that affects economy, environment, and people, and thus, is directly connected with sustainability. This fact offers the necessary theoretical background and consists a chance for corporations to incorporate LD inside their Corporate Social Responsibility (CSR) policy (Panagiotopoulos 2018).

Sustainability and CSR

The concept of sustainability has enriched the philosophy of ecology by suggesting the necessity of a dynamic balance among environmental preservation, society and economy (Jordan and Lenschow 2008). The term economy represents

any technological and commercial activity of people.

CSR is the concept that calls corporations to include social and environmental concerns in their decision-making processes and in their relations with their stakeholders (European Commission 2001). Modern corporations make efforts to comprehend the concept of sustainability and its materialized expression with the form of CSR in their business practices. The most intense type of CSR, strategic CSR calls firms to incorporate sustainability principles through CSR programs in their everyday activities (Mc Williams and Siegel 2011). CSR has three main fields of interest (European Commission 2001):

- Economy referring to the market where a firm is active
- Society concerning the local community of a place where a company is located, the people who are the customers of the company and the employees of the company, too.
- Environment that includes aspects like environmental preservation, waste management, energy consumption, etc.

The key element in the modern consideration of CSR is stakeholders. Everyone who is directly or indirectly related or affected by the operation and the decisions of a company belongs to the wide group of stakeholders. CSR underlines that every company should respect the interests of its stakeholders and consider them during decision-making process. The era when a company had as only target the maximization of the wealth for its shareholders has passed in accordance with the theory for CSR and sustainability (Carroll 1991).

Lighting Design

Lighting Design (LD) comprises a process for the incorporation of the element of light in building total architecture. LD must contain provisions for the existence of light where is needed and on parallel to achieve to reduce light where is not necessary or desirable. A successful modern LD

should respect sustainable values (Gordon 2014, p. 204).

Environmentally Responsible Lighting Design (ERLD) is called the sector of lighting architecture that considers environmental protection as part of its targets. ERLD is based on sunlight and daylight besides artificial lighting. The combination of sunlight and artificial lighting consists the “passive approach” of Lighting Design in bi-climatic architecture which consists part of ecological architecture (Al-Sallal 2016).

ERLD has as main element the use of daylight along with the use of artificial light. The artificial light is used complementary when the natural light is not enough to cover the lighting needs of a space. The optimal use of daylight implies the ability to control it because plenty daylight could cause issues like glaring and overheating which can create uncomfortable or even dangerous living and working conditions. For that reason, another important element of ERLD consist shading. ERLD could be restructured to Sustainable Lighting Design (SLD) through the angle of CSR concerning corporations by taking into consideration social, environmental, and economic parameters. Especially, SLD could offer various benefits to an organization and that profit operates as reasoning for the necessity and the advantages of CSR in business world. Furthermore, the incorporation of lighting design programs in CSR policies of firms would upgrade the general interest concerning the value of natural light for human health and underline its importance for a healthy and qualitative working environment.

The Benefits of Daylight in Humans

By the term daylight is described any type of natural light that originated from the sun directly or indirectly. Daylighting concerns the delivery and distribution of light from the sky and the sun to a building interior and the provision ambient and/or task lighting to cover the visual and biological needs of its users (Al-Sallal 2016, p. 63). Natural light consists of three discrete categories of light: (a) the light that comes directly from the sun, (b) the daylight that is the result of the

scattering of sun beams in the atmosphere, and (c) the daylight that is the result of the reflection of sun beams in the land and other surfaces (Al-Obaidi et al. 2016, pp. 129–131). Thus, there are three subcategories of natural light that have different characteristics and possibilities to be exploited with various technical means like windows, atriums, etc. The exploitation of natural light for the coverage of lighting needs in corporate buildings hides a plethora of benefits for environment, people, and economy, covering all the three poles of interest of a CSR strategy.

At first, especially direct sunlight expedites the secretion of serotonin hormone which is vital for the adjustment of circadian cycle, spiritual clarity, and mental health (Boubekri 2014, pp. 31–34). The circadian rhythm is regulated through the secretion of serotonin. Lack of natural light during the day, as it happens inside most of the corporate buildings with the fluorescent lamps, implies low levels of serotonin. This absence of serotonin is replaced by the secretion of melatonin which is related with drowsiness and results in high risk for occupational accidents and deaths, along with low professional performance by employees. Seasonal Affective Disorder (SAD) is another disorder that relates to the absence of daylight in the everyday life inside corporate premises. SAD is considered a type of depression directly caused by the limited access to daylighting. It is more popular in north countries during the winter period, when sun stays less on the sky and the duration of night is bigger. The most usual symptoms of SAD are a strong sense of tiredness, increased need for sleep, craving for the consumption of hydrocarbons, depression, anxiety, low morale, and possibly other health disorders as consequence of the previously mentioned conditions. The exposure to natural light is considered a main therapeutic agent for SAD and consequently windowless corporate premises where employees spent at least one-third of their day do not support positively their health condition (Boubekri 2014, pp. 31–35). Moreover, the unlimited access to direct sunlight and the view of external environment through proper openings provide a mental and optical relaxation to employees and assist them to maintain good mood through the whole work hours.

Situations like depression, anxiety, low morale, and lack of motivation for action are indications of psychological and mental illnesses which consist a serious and intense phenomenon in modern societies especially in developed world. These disorders of people cause genitive financial impact to companies. Employees who suffer from SAD for example take more day-leaves from the office either for medical reasons or nor, present low productivity, lack of motivation, and poor performance in brainstorming activities. It is estimated that depressed people lose approximately 1 h of real productive and creative work in daily basis due to their situation (Boubekri 2014, pp. 34–35). Limited access to daylight has been related with low sleep quality too. All these symptoms make employees with poor quality of sleep to underperform in their work, to have limited mood to cooperate, difficulties to focus on their tasks, lack of calmness, and last but not least higher possibilities to be involved in accidents during their work hours (Boubekri 2014).

Natural light is considered of superior quality than artificial lighting. The combination of sunlight and daylight is considered by specialists the best light sources for human eyes. There are several benefits that source from natural light. Everyday access to daylight through working places provides a sense of connection between employees and natural environment. Natural light offers a balanced color spectrum because its energy peaks are slightly in the blue and green portion of the visible spectrum. The term “quality of light” means a holistic approach that embraces parameters like the distribution of light, color rendering, flickering of light, brilliance, and variability. It is representative of the higher quality of natural light that less quality of the first is need for the implementation of a project in comparison with the quantity of artificial light that is needed for the same project.

A Protocol for Sustainable Lighting Design

LD targets to assure safety in the working environment and optical comfort for employees. The basic

aim of ERLD is the production of the same lighting result with less quantity of energy and, thus, less burden for environment. Sustainable LD involves control of light, glare, and energy usage, to be in compliance with ecological principles (Gordon 2014, pp. 204). Modern light designers should be aware of the impact of natural light and/or its absence in biological functions and performance of people (Gordon 2014, pp. 216). The interactions among the three main fields of CSR, the relevant lighting policies and the potential sustainable targets are presented in Table 1 creating a solid theoretical background for the establishment of Sustainable LD and its adoption in CSR strategies.

Benefits from Sustainable Lighting Design

The embodiment of natural light as central ingredient of lighting design in corporate buildings provides various benefits to the company that designs and apply such sophisticated CSR policy (Panagiotopoulos 2018a):

- Savings of energy because artificial light substitutes less times daylight.
- Savings of energy due to the reduced use of air conditioning for heating and cooling.
- Savings of money due to the use of solar panels in corporate premises.
- Money savings through the improvement of working environment and the aftermath limitation of employees' absenteeism due to medical reasons in correlation with the limited access to daylight.
- Financial profit due to increased productivity of employees. The increased use of daylight in working environment increases employees' health, mood, and creativity and supports them to fulfill their duties.

Sustainable Lighting Design in Twenty-First Century

SLD can use several ways and technological achievements for the proper mix of natural and

Sustainable Lighting Design, Table 1 The Sustainable Lighting Design Protocol comprises the interconnections that arise among CSR fields, CSR goal setting, and the relevant lighting parameters (Panagiotopoulos 2018b, 2019)

		View of Exterior Environment

artificial light. Shading is an important parameter in SLD. Means for shading could be placed either in the external or internal environment of a corporate building. An advanced ability for shading equals an advanced control of daylight inside a building. Basic idea of SLD is to achieve the desired lighting conditions in a work space with daylighting without additional thermal load and glare in comparison with the available artificial lighting solutions (Lechner 2015). The proper technical means for an homogeneous diffusion of daylighting are: skylight/roof light, roof monitor/clerestory, sawtooth, courtyard and lightwell, atria, light tubes, and light ducts (Al-Obaidi et al. 2016).

Although theoretically lighting needs of corporate buildings could be covered by a combination of natural and artificial lighting, the most popular solution in use consists of fluorescent lamps, and low ceilings. This solution provides stable and homogenous conditions inside a corporate building close or far of the openings of the building and independently of the climate conditions of the place where the building

is. Furthermore, it saves space which previously was used for internal atriums that were planned for the introduction of daylight into the internal of a building. This popular solution causes an increased consumption of energy and high gas emissions because it avoids taking any advantage of the natural conditions of each place of earth since suggests the same for a place in Norway with limited sunshine and a place in Greece with sunshine the most days of the year. This established concept seems that additionally disconnects employees from the external environment and limits them inside the same artificial microclimate (Boubekri 2014).

Ideally, sun light could be used in higher percentage instead of artificial light in corporate premises. However, this is not so simple, because it is not easy for daylight to enter with homogeneity inside the working spaces and it is accumulated in places closed to windows. Glare consist another challenge for the spaces closed to windows. Moreover, direct sun beams multiply the thermal load in the spaces closed to the windows and the consequent need for cooling will result in higher

consumption of electricity. The proper exploitation of natural light should be based on a detailed lighting design that includes architectural openings, shading systems, and lighting automation systems with photocells and sensors of motion. The exploitation of natural light in corporate premises could result in energy savings of 20–40% due to reduced lighting and heating ventilation and air-conditioning (HVAC) needs (Boubekri 2014, p. 15). The savings could be higher whether there is a total CSR plan for the optimization of energy usage that involves automatic control system for lighting and HVAC, timers, occupancy or motion sensors, photosensors or daylight sensors (photocells are a subsystem of them), dimers, means for shade, etc. (Gordon 2014, pp. 254–257).

The upgrade of lighting design of corporate premises to an important part of a total CSR policy for the optimization of energy usage could offer several benefits in various fields like financial savings through a reduction in electricity bills, better working conditions for employees which support their good health and their productivity, and less gas emissions from the building operation. It is not easy for a corporation to record all these advantages with a quantitative manner. However, many of these benefits could be quantified through energy savings, increase in sales, less medical leaves for employees, lower accident rates, etc.

Epilogue

SLD is a new challenge for CSR specialists as for lighting designers, too. It demands deep perusal of light in order a spherical picture of its interactions to be obtained. A complete study for the lighting design of a corporate building should take into consideration parameters like the total life cycle assessment for the building, purchase cost for artificial lighting, construction cost for openings, energy consumption, gas emissions percentage, lighting performance, life span, possibilities for recycling and waste management, maintenance, replacement cost, etc. (Zheng 2016, pp. 88–96). Furthermore, it should consider the effect of

natural light in better and healthier working conditions, the improved productivity of employees due to better lighting conditions, etc. Finally, SLD consists a call for the consideration of lighting design in multilevels in compliance and proportionally with the sustainability principles, and for the deep comprehension of its interscientific interactions with economy, environment, and human health and performance.

Summary

Lighting Design (LD) has been an underestimated parameter in the design of corporate buildings and workplaces for decades. The development of Environmentally Responsible Lighting Design (ERLD) is deemed an upgrade for the comprehension of the impact of light in corporate environment and natural environment. However, a better perusal of the implications of LD reveals that light has the potential to affect the environmental footprint of a company, the health and safety in workplaces, the productivity of employees, its energy costs, and its relations with local community. This fact entails that light could be transformed into a basic sustainability parameter for a corporation since affects all the three main poles of sustainability: environment, economy, and society. Moreover, this realization indicates a chance for the incorporation of the element of light into the Corporate Social Responsibility (CSR) policy of organizations providing a plethora of advantages for employees, society, and the company itself, and additionally possibilities for assessment of such initiatives. This fully comprehension of the sustainable potential of light leads to Sustainable Lighting Design (SLD) as a necessary step for the better exploitation of light in favor of humans, environment, and companies.

Sustainable Logistics

Carsten Deckert

Faculty of Mechanical and Process Engineering,
Hochschule Düsseldorf, University of Applied
Sciences, Düsseldorf, Germany

Synonyms

City Logistics; Green Logistics

Definition

Sustainable Logistics is the application of principles from sustainability to logistics, i.e., the functions of transportation, warehousing, and packaging. It is a part of Sustainable Supply Chain Management and includes the concepts of Green Logistics and City Logistics.

Green Logistics is a logistical concept, which mainly deals with the environmental dimension of the Triple Bottom Line and aims at the alignment of the logistical functions with the targets of environmental sustainability, i.e., improvement of resource efficiency and reduction of emissions. In essence, Green Logistics combines the “six R’s” of logistics with the targets of environmental sustainability concerning resource consumption and environmental friendliness. This means that the task of Green Logistics is to make the right quantity of the right product available at the right place and the right time in the right condition for the right cost (“six R’s”) while keeping resource consumption and emissions as low as possible (environmental sustainability).

City Logistics is the improvement of the supply of urban areas with goods. This includes not only deliveries but also return logistics. In contrast to city planning, City Logistics mainly uses existing public infrastructure. Targets of city logistics are the relief of the strain on transport infrastructure (e.g., less traffic congestion, fewer accidents) and the reduction of emissions, particularly direct emissions such as noise, particulate matter, and nitric oxide.

Introduction

Due to the interlacing of economies and the liberalization of world trade, the global flow of materials and goods is steadily increasing. In such a globalized world, there is an increase in logistical activities such as transportation, warehousing, and packaging. This means that the negative impacts of logistics on the environment will, in all likelihood, also increase.

Every human activity has potentially negative impacts on the environment in two areas: resource consumption and emissions of harmful substances. Resources can be energy, raw materials, water, air, and space. Emissions can appear in the form of pollutants, waste, radiation, noise, and disfigurement of the landscape. Typical impacts of logistical activities with regard to resource consumption are fuel consumption for transportation, energy consumption, and use of space for warehousing and material and energy consumption for packaging. Typical emissions of logistical activities are exhaust fumes, greenhouse gases and noise for transportation, greenhouse gases (indirect emissions), and disfigurement of landscape for warehousing as well as waste for packaging (Deckert 2015, 2017).

Another issue affecting logistics activities is the megatrend of urbanization. More and more people around the globe live in cities, and cities gain in size leading to what is called mega-cities with more than ten million inhabitants. This

leads to a growing delivery volume into urban areas, which is often comprised of many small, just-in-time deliveries. Typical logistical problems in supplying densely populated urban areas with necessary goods are constrained access to inner cities due to a rivalry between delivery vehicles and passenger vehicles for the same space on the road, an increase in traffic jams, accidents, and emissions as well as longer transportation times due to traffic congestion and increased surface size of the city. All this decreases the logistical service as well as the quality of living in cities (Stodick and Deckert 2019).

Key Issues of Green Logistics

According to the Council of Supply Chain Management Professionals (CSCMP 2013), logistics can be defined as the “process of planning, implementing, and controlling procedures for the efficient and effective transportation and storage of goods including services.” Functions of logistics are transportation, warehouse management, and packaging. Since Green Logistics is the alignment of logistical functions with the improvement of resource efficiency and the reduction of emissions, it contains measures for Sustainable Transportation, Sustainable Warehouse Management, and Sustainable Packaging (see Fig. 1).

Transportation is the movement of goods between different locations using different

Sustainable Logistics, Fig. 1 Green Logistics Framework (Deckert 2017)

modes of transport. Modes of freight transport can be road transport, rail transport, pipeline transport, inland waterway transport, ocean or sea shipping, air transport, or intermodal transport (i.e., a combination of different modes of transport) (Chopra and Meindl 2013; Grant 2012). According to McKinnon (2015), the main parameters of *sustainable transportation* are modal split, average number of changes of transportation mode, average length of haul, average load on laden trips, average percentage of empty runs, other externalities per vehicle-km and per unit of throughput (e.g., noise, accidents), energy efficiency of transport vehicle, and emissions per unit of energy. Sustainable transportation can, thus, be achieved by avoidance of transports (e.g., digitization of goods), reduction of number of transports (e.g., through increased load utilization), and length of transport route (e.g., through route planning) as well as reduction of harmfulness of transports (e.g., development of environment-friendly propulsion technologies, use of environment-friendly modal split) (Deckert 2015, 2017).

Warehouse management can be defined as “that part of a company’s logistics system that stores products [...] at certain nodes in the firm’s supply chain, and provides information to the firm on the status, condition and disposition of items being stored” (Grant 2012). Sustainable warehouse management primarily aims at low energy consumption of the warehouse (and, thus, low indirect greenhouse gas emissions). Low energy consumption of a warehouse can be achieved mainly by measures on electricity and lighting in the warehouse or on heating and cooling systems of the warehouse. Other issues of sustainable warehousing are environment-friendly means of conveyance and reduction of storage space (Deckert 2015, 2017).

Packaging comprises the functional use of packaging systems such as transport packaging as well as the employment of loading devices such as pallets or containers. Sustainable packaging focuses on material efficiency concerning packaging design and on waste treatment after packaging use. Material efficiency in packaging can be achieved by preventing packaging, by reducing packaging quantity and/or harmfulness,

by reusing packaging through reusable packaging systems, or by recycling packaging materials. The main task of sustainable packaging design is to balance the function of sustainability with the established packaging functions (e.g., protection and preservation of the packaged good) (Deckert 2015, 2017).

Key Issues of City Logistics

Taniguchi et al. (2001) define City Logistics as “the process for totally optimizing the logistics and transport activities by private companies in urban areas while considering the traffic environment, traffic congestion and energy savings within the framework of a market economy.” In essence, this means to improve the supply of urban areas with necessary goods using the given transport infrastructure. A focus of City Logistics is typically on transport management within urban areas containing such fields as urban consolidation centers (UCCs), intelligent transport systems (ITS), and environment-friendly means of transport (Deckert 2015).

The measures of City Logistics typically make use of the following mechanisms (see Fig. 2; Deckert 2015, 2017; Stodick and Deckert 2019):

Consolidation of transports and matching of the flows of goods: Typical measures are the freight consolidation in urban consolidation centers (UCCs) at the edge of town as well as the use of intelligent transport systems (ITS) to optimize transport routes and to track and trace deliveries.

Separation in Space and Time: Measures for separation in space include separate transport lanes as well as air or underground transport. Typical examples of measures for separation in time are deliveries outside of the rush hour (e.g., nighttime deliveries).

Use of Environment-friendly Means of Transport: Typical measures include the application of environment-friendly delivery vehicles such as electric vehicles or the use of existing passenger infrastructure for freight transport, e.g., subway or tram.

Sustainable Logistics, Fig. 2 Mechanisms of City Logistics (Stodick and Deckert 2019)

A measure in City Logistics can also combine two or more mechanisms. A typical example is the concept of microdepots as used by CEP service providers (courier, express, parcel). A microdepot is an interim storage in the city – usually a container deposited at the center of gravity of the respective distribution area – from which the parcels are delivered to the recipient using environment-friendly means of transport such as cargo bikes. Microdepots divide the last mile of delivery into two steps: firstly full-truckload-delivery from depot of the CEP service provider to the microdepot (second last mile), then delivery of individual parcels from the microdepot to the final recipients (very last mile). This means that the concept of microdepots combines the consolidation of transports on the second last mile with the use of environment-friendly means of transport on the very last mile (Stodick and Deckert 2019).

According to Crainic et al. (2009) the main target of city logistics is the reduction of the “nuisances associated to freight transportation in urban areas while supporting their economic and social development.” The “nuisances” can be divided into strain on the transport infrastructure (e.g., traffic congestion and accidents) as well as noise and emissions such as greenhouse gases and exhaust fumes. The measures of city logistics have different impacts on these “nuisances.” The consolidation of freight leads to

fewer delivery vehicles in the city, which reduces emissions and traffic congestion. Separation in space and time mainly reduces traffic congestion and accidents. Environment-friendly means of transport reduce the emissions per vehicle and – in case of new propulsion technologies such as electric engines – the noise level. If smaller vehicles such as cargo bikes are used, as in the case of microdepots, there is also a reduction of road blockage and traffic congestion (Stodick and Deckert 2019).

Summary and Outlook

As a logistical concept focusing on environmental sustainability Sustainable Logistics includes Green Logistics (the alignment of logistical functions to environmental sustainability) and City Logistics (the improvement of supplying urban areas with goods). In the full meaning of sustainability, social issues should also be included in this approach to achieve a full Triple-Bottom-Line view of logistics. While City Logistics includes some social aspects (e.g., noise and traffic congestion), Green Logistics contains none. Social issues of logistics are, e.g., noise emissions from transportation activities and their impact on human wellbeing (e.g., in the vicinity of warehouses), accidents of delivery vehicles and safety issues impacting other traffic participants as well as work conditions and remuneration of logistics

workers. Future research should integrate these issues into a holistic and integrated model of sustainable logistics.

The three functions of logistics are not independent, and measures in one area usually have trade-offs in other areas. Isolated measures taking into account only one logistical function run the risk of ignoring impacts on the other functions. In the future, trade-offs between the functions of sustainable transportation, warehousing, and packaging should be researched in more depth. One example of the interdependences of the functions is that a reusable packaging system increases the resource efficiency in packaging but usually also leads to higher emissions in transportation for return logistics.

One way to increase our understanding of the impacts and trade-offs of different measures in sustainable logistics is to quantify the effects these measures have on different dimensions of environmental sustainability. An important area of research is to develop meaningful and comparable measurements for resource consumption and emissions. One example is the standardization and harmonization activities surrounding the Transport Carbon Footprint to enable comparison and benchmarking of different transport solutions (Deckert and Görs 2018). Another issue is that in an economic context measurements should also be easy to implement to ensure a wide application, especially in small and medium-sized enterprises.

Definition

Sustainability marketing can be defined as *“the planning, coordination, implementation and controlling of all market transactions in such a way that a sustained satisfaction of the needs of current and potential customers toward the achievement of corporate objectives is granted, while at the same time contributing toward reducing ecological and social impacts and restoring social and ecological health”* (Kirchgeorg and Winn 2006 p.176). Further, Jabbour (2010 p.1223) states that organizations should incorporate sustainability marketing practices throughout the levels of management. As there appear diverse concepts that are interchangeably used by sustainable marketing phenomenon in the pertinent literature such as “eco-friendly marketing,” “environmental marketing,” “corporate environmentalism,” “ecological marketing,” or “green marketing” (Pane-Haden et al. 2009), all of which notions imply to the integrated marketing and management policies/practices, distributing responsibilities for the implementation of environmental and sustainability matters via developing sustainable strategies, and creating different competitive advantages such as declining extra costs (i.e., energy and material), enhancing profits (i.e., differentiation), and improving stakeholder relationships (Ambec and Lanoie 2008).

In that vein, different scholars conceptualize and describe these alternatively used notions in

different ways in the pertinent literature. For example, Banerjee (2002 p.181) defines corporate environmentalism concept as “the organization-wide recognition of the legitimacy and importance of the biophysical environment in the formulation of organization strategy, and the integration of environmental issues into the strategic planning process.” In this sense, while some researchers assert that corporate environmentalism consists of waste reduction, which in turn improves revenue maximization, other scholars rely upon the premise that it captures far more than waste minimization. On the other hand, corporate sustainability expands beyond the contamination retrenchment and requires continuous improvement within an organization (Pane-Haden et al. 2009). To achieve sustainability goals, economies should change their view from a growth orientation to steady-state orientation, in which the rates of consumption and pollution do not extend the capacities of a country (Daly 1996). Overall, sustainability implies to “the development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (Brundtland Commission 1987).

Key Issues

As being alive depends upon some regular functions of the biosphere, it is relatively revealed that human behaviors heavily damaged the climate (Agatiello 2009). Besides, the extent of human activities has gradually increased each year with incremental impacts on the global context (Hart 1995). On the other hand, the population over the world has been increased from two billion to approximately seven billion after the World War II, anticipating reaching at around 10 billion by the end of 2050. In a parallel vein, an increased population results in harmful ecological effects. To address these issues, the United Nations Stockholm Conference has determined on an action plan and the Brundtland Commission has published their report in 1987, which covers around four subjects: (a) regulating the impacts of populations on the climate, (b) ensuring food

preservation, (c) allocating sufficient resources in an effective manner, and (d) organizing sustainable systems (Brundtland Commission 1987). In this context, Shrivastava (1995) declared that Brundtland Commission put special emphasis on the concept of “ecologically sustainable development” (ESD), which implies to dealing with both economic and environmental matters simultaneously.

The Historical Evolution of Sustainable Marketing

The concept of sustainable marketing is an evolving process, which dates to 1940s with the approval of Human Rights by United Nations, which is postdated by economic and socio-cultural rights in the 1960s, and lastly ecological matters was popularized as risen topic of 1970s. Owing to the Brundtland Commission Report, a set of environmental protection statements were declared, respectively, such as the “Montreal Agreement” in 1989, the “Basel Treaty” in 1992, and the “Kyoto Protocol” in 1997. In this sense, Kyoto Protocol endeavors to reduce greenhouse gas emissions throughout the world and accepts the estimation of costs associated with global warming within a system. Hence, “Kyoto Protocol” plays a judgmental role in giving priorities to the accountability of the companies regarding the natural environment (Albino et al. 2009). Nevertheless, Shrivastava (1995) has indicated that not only firms generate the wheels of sustainability but also consumers and governments have some responsibilities in terms of consuming wisely and regulating with environmentally sustainable policies.

Further, Industrial Revolution, initiating in the late 1700s in England, has disseminated over North America as there exist controversies about the start and end dates. This era is regarded as the most accelerated period in terms of increasing the level of consumption, contamination, and deterioration (Pane-Haden et al. 2009). Thereafter, this period was followed with a transmission time towards a capitalistic economy where individuals and organizations put emphasis on revenue-

orientation and increased production levels (Hobsbawm 1975). As the population volume rapidly grows, it also results in increased levels of the resource deterioration and ecological degradation (Pane-Haden et al. 2009). Afterwards, nineteenth century has faced with important historians, philosophers, naturalists, and writers who lead to the “Conservation Movement,” which enhances environmental consciousness level of individuals in the late 1850s (Udall 1963). This movement was targeted to decline the irresponsible deployment of the resources owing to industrialization, leading to several government regulations such as “the Forest Reserve Act” in 1891 and “the Rivers and Harbors Act” in 1899 (Pane-Haden et al. 2009).

Given heightened consumer awareness on environmental matters, the governments began to establish stricter regulations regarding the environment (Menon and Menon 1997). Thereafter, organizations started to distribute their budgets for ecological aids with an intent of meeting with environmental legislations. In relation with academic standpoint, the new concepts such as “holistic/strategic social responsibility,” “cause-related marketing,” and “sustainability” were initially emerged in the extant body of the literature (Varadarajan and Menon 1988).

During the 1990s, heightened pressure of ecological activists on governments was received greater attention of the media, which in turn revitalizes the environmental matters again (Peattie 1995). However, Nattress and Altomare (1999) considered this era as proactive responses of corporations against ecological problems. In this sense, it should be noted that organizations started to be aware of environmentally friendly behaviors that may yield financial benefits to the companies. In addition, the terminology of “eco-efficiency” has become very popular among organizations in the marketplace. Further, firms need to understand whether implementing environmental practices provides the opportunities of prestige and profit. Also, environmental activities not only complicate the nature of the product, which makes it harder to imitate by rivals, but also reduce the negative ideas of customers and media (Walley and Whitehead 1994). In terms of scholarly

contributions, some new concepts such as “environmentalism” (e.g., Drumwright 1994), “social marketing” (e.g., Andreasen 1994), “enviropreneurialism” (e.g., Menon and Menon 1997), and “corporate social responsibility” (e.g., Brown and Dacin 1997) were emerged in the extant literature.

In the 2000s, there has been a burgeoning concern on ecological issues owing to the effect of globalization, rapid growth in competition, increased conscious level of consumers, and high global warming threats (Baker and Sinkula 2005). Moreover, organizations understand that sustainable issues should be engaged in all their firm behaviors to survive in these highly competitive and dynamic environments. During that period, scholars put great attention on the subjects such as corporate environmentalism (e.g., Banerjee et al. 2003) and market-oriented sustainability (e.g., Crittenden et al. 2011).

In sum, even though sustainable marketing has been emerged in 1990s in the pertinent literature, a sharp increase has been recognized in 2000s in the last two decades (Chabowski et al. 2011). However, a wide range of academic research subjected to environmental matters dates back to the 1960s with the emergence of the concept of “societal marketing” (Kotler and Levy 1969). Because environmental strategies have incrementally received a great attention of academics, existent body of intellectual knowledge reveals a number of different concepts related to the sustainable marketing named as “cause-related marketing” (e.g., Varadarajan and Menon 1988), “social marketing” (e.g., Andreasen 1994) and “environmental marketing” (e.g., Drumwright 1994), “enviropreneurial marketing” (e.g., Menon and Menon 1997), “corporate social responsibility” (e.g., Brown and Dacin, 1997), “corporate environmentalism” (e.g., Banerjee et al. 2003), and “market-oriented sustainability” (e.g., Crittenden et al. 2011).

Summary

Last two decades have received an increased interest on natural environment by governments, policy makers, companies, and the community over

the world. Several researchers have uncovered the possible ecological effects of increased number of world population, industrialization activities, and the exploitation of nonrenewable resources. Although industrialization that lasts for more than a century has provided some opportunities, it has also resulted in environmental corruptions (Shrivastava 1995). There exist several climate deteriorations such as increased level of oceans, ozone depletion, increased degree of acid rains, reduced biodiversity, global warming, and soil erosion (Hart 1995). The sustainable marketing concept has been received great importance of both marketing scholars and marketing managers, as a wealth of academic research acknowledges the importance of the subject in the extant literature. This chapter is aimed to present the definition of sustainable marketing via presenting similar concepts’ definitions, which is followed by key issues in sustainable marketing and the historical evolution of the subject.

Synonyms

Green marketing; Socially responsible marketing; Societal marketing

Definition/Description

“Sustainable marketing” is a holistic approach to marketing theory and practice that takes goals from all three pillars of triple bottom line (TBL), namely, environment, society, and economy. It stands for a balanced and equitable development with integrated marketing effort and through customer satisfaction. Within marketing thought, “green marketing,” which is sometimes used synonymously with ecological marketing or environmental marketing, focuses on the reduction or elimination of negative environmental impact caused by marketing strategy and practice. These negative impacts reside in the way by which products and services are designed, the resources they consume, waste generated by excessive packaging, and distribution structures that depend on nonrenewable and pollutant resources. On the other hand, triggered by the consumerism movement, “societal marketing” focuses on marketing strategy and practice that causes overproduction

and overconsumption, provision of goods and services that threaten human health or safety, and societal consequences of environmental damage caused by marketing activity.

Sustainable marketing is a holistic view of marketing's role in the quest for sustainable development. It requires the convergence of green and societal marketing for a responsible design and development of goods and services that enhance quality of life and an equitable distribution of those goods and services between industrialized and non-industrialized nations of today and tomorrow. At the same time, sustainable marketing calls for a shift from a dominant focus on wants to needs in order to prioritize sustainable utilization of resources. To achieve the transformation of conventional marketing toward sustainable marketing, a critical marketing approach is required that challenges the fundamental objectives of marketing based solely on economic development.

Introduction

Sustainable marketing is marketing within and supportive of sustainable economic development (van Dam and Apeldoorn 1996, p. 46). Based on the widely accepted definition in Brundtland Report (WCED 1987), such a development requires equitable and balanced growth within and across different generations that focuses on not only the physical environment but also societal needs. Therefore, sustainable marketing is a contemporary marketing thought that challenges the fundamentals of conventional approaches to marketing and addresses how "mutually satisfying exchange relationships" (Baker 2010, p. 3) can be achieved while eliminating the damage on environment and considering societal needs at large.

Although it is a relatively newer concept, sustainability was on the agenda of modern marketing thought since the 1960s and 1970s. Green marketing has emerged and was established as a strong domain following the ecological and environmentalist movements of these early eras. Similarly, societal marketing and social marketing

have emerged as a response to raising consumerism thought in parallel. The aim of this entry is to provide an understanding of these separate marketing domains and then to synthesize them for conceptualizing sustainable marketing.

Green Marketing

The negative impact of industrial activity and commerce on the physical environment such as increased pollution, extensive use of non-renewable resources, and accelerating levels of waste has been on the agenda of governments, society, and business for many decades. Green marketing focuses on the relationship between marketing and environment. In particular, it covers the marketing activities that reduce the negative environmental impacts of products, services, or production systems while, at the same time, promote products and services that cause less or no harm to the environment (Peattie 2001). Ecological marketing and environmental marketing are terms that are sometimes used synonymously with green marketing in different sources, but in fact they refer to earlier eras in green marketing's historical development.

At the end of the 1960s and the beginning of the 1970s, the ecological marketing movement challenged conventional marketing thought and demanded environmental considerations to be incorporated into marketing practice. The main causes of this were increased environmental pollution and acknowledgment of the limits to natural resources that were abundantly used for centuries. Ecological marketing was defined as the study of negative and positive impacts of marketing action on pollution, energy depletion, and non-energy resource depletion (Henion and Kinnear 1976). This era had a relatively low impact in marketing practice because it had too much of a local focus on selected industries based on limited environmental indicators and couldn't influence a large segment of companies or consumers (Peattie and Charter 2003). However, it triggered the introduction of laws and regulations that forced businesses to take measures on their activities that created

negative impact on the environment (Menon and Menon 1997).

Then, following the big environmental disasters such as Chernobyl or Exxon Valdez oil spill and the publication of Brundtland Report (WCED 1987), the late 1980s experienced the second wave of environmentalist movement which this time was widely accepted by marketing, consumers, and the society at large. Environmental considerations became a part of marketing strategy for organizations as the number of environmentally conscious consumers increased and ability to offer green products and services began to provide competitive advantage. Strategies such as greening the production processes through input reduction, decreasing packaging, and switching to reused or recycled materials for production introduced cost advantages for companies.

One way to understand how green marketing is applied in practice is by using the marketing mix concept. Organizations introduce green product, green price, green promotion, and green distribution strategies for incorporating environmental considerations into their marketing activities. Green product strategies range from product design for environment, replacing virgin raw materials with environmentally friendly raw materials, decreasing production, or consumption waste to elimination of planned obsolescence, using degradable packaging, or eco-labelling of products.

Green pricing is related with internalizing the external costs of production and consumption. It is not only about adding the “green premium” to prices or introducing inferior products through recycling or refurbishing. Cost reductions in the long run due to decreased resource usage serve as competitive avenues for green pricing. Furthermore, new pricing strategies such as pay per use reduce overproduction and contribute to environmental sustainability.

Green promotion is a strategy that needs careful handling. Marketing communications for environmental products and services are necessary to inform the consumers about green alternatives in the market. However, accuracy about the environmental performance of products and services is essential. Over-promising with green

promotion might result in green washing accusations.

Finally place strategies have significant impact on green marketing practice because of the heavy dependence of transportation on fossil fuels. Distribution network design, capacity utilization in transportation and warehousing, transport mode selection, and customer service levels are various physical distribution decisions that impact environmental performance.

Despite the wide recognition of green marketing, skepticism has been raised to narrow applications of green marketing strategies (Peattie and Crane 2005) and inability of marketing to incorporate environmental considerations as a strategic tool (Polonsky and Rosenberger III 2001). Green marketing is perceived as a hype or a myth as long as more radical change in corporate philosophy and action doesn't take place. Transformative green marketing that alters the financial performance measurements and perceptions of value is called for a real change (Polonsky 2011). Convergence of societal considerations with environmental considerations and a focus on sustainable marketing is another solution (Peattie 2001) that is suggested to have a more holistic understanding of green marketing.

Societal Marketing

The raising ecological considerations triggered skepticism about conventional marketing practice that caused overproduction and overconsumption. The relationship between increasing negative environmental impact and free use of resources that are considered infinite started being noticed widely which pointed out the negative societal impact caused by marketing activities. Critics started to call for a focus on human needs instead of business needs, expansion of marketing to social areas such as population control, or education support and a general business orientation shift from solely profits to societal impact (Takas 1974). Consumerism movement spread widely among the new highly educated consumer profile of the 1970s and called for marketing action

against irresponsible corporate behavior (Abratt and Sacks 1988).

Societal marketing emerged as a response to these critics, and it is defined as the incorporation of societal considerations to marketing strategy and practice regardless of the object of exchange (El-Ansary 1974). This object of exchange can be a product, service, social cause, a person, or an idea. The focus of integrated marketing effort in its conventional form is customer satisfaction as the key to attaining long-run profitability. Societal marketing extends this focus and includes long-run customer welfare to the objectives of marketing while maintaining long-run profitability (Kotler 1972). In addition to achieving customer satisfaction under fair conditions to customers, marketers need to support customers to make intelligent purchase decisions and avoid making firm decisions that have negative impacts on society at large (Schwartz 1971). Therefore, societal marketing extends the exchange actors from sellers and buyers to the larger task environment that includes employees, competitors, suppliers, and even the larger society considering that anything that is done for the benefit of the society will provide benefits to the firm in the long run.

Social marketing, which sometimes might be confused with societal marketing, is a different concept that similarly focuses on society but has a relatively limited focus onto object of exchange. Social marketing is defined as the application of standard marketing tools and practices to influence the acceptability and dissemination of social ideas or causes (Kotler and Zaltman 1971). Some examples to these social ideas can be safe driving, anti-smoking, recycling, or responsible consumption. The marketing of these social ideas can be done by for-profit or non-profit organizations, but the essence is the utilization of conventional marketing knowledge while marketing these ideas. Based on this definition, societal marketing is a larger concept that requires consideration of society at large while conducting marketing activities whether to market commercial goods and services or social ideas. It is the incorporation of corporate social responsibility into marketing thought.

Societal marketing, which is sometimes used synonymously with socially responsible

marketing, has gained attention throughout the many years since it was introduced the first time. Alongside with consumerism movement, it influenced marketing practice in terms of safe and responsible product design, marketing communications that educate consumers for responsible consumption, advertising that avoids overconsumption or deceptive promotion, fair pricing, and fair distribution. Consumerism movement triggered the introduction of new laws and regulations that protect consumer rights, and these laws and regulations affected changes in the marketing mix toward social responsibility.

Despite the increase in interest to both green marketing and societal marketing, one can't say that the balance between those concepts and economic considerations is achieved. Takas (1974, p. 3) once stated that "for a businessman a product is not a societal consideration; it is something the factory can make, the warehouse is full of, and the sales department has got to move at as great a profit as possible." It is possible to see that this view still holds true in some cases especially when the societal or environmental interests collide with business interests. A more holistic and balanced approach to green and environmental marketing which also considers the requirements of conventional marketing is represented by sustainable marketing concept.

Sustainable Marketing

Sustainable development is defined as a balanced and equitable path to development that depends on three main pillars which are also known as the TBL. TBL stands for a balance between social, environmental, and economic pillars which are illustrated frequently with a Venn diagram. Departing from TBL concept, sustainable marketing, in this entry, is defined as the integrated marketing effort that aims to achieve customer satisfaction for maintaining balanced and long-run environmental, societal, and economic performance. Sustainable marketing is a larger concept than green marketing or societal marketing that includes the goals of both. Figure 1 below shows sustainable marketing and its main pillars.

Sustainable Marketing II,

Fig. 1 Sustainable marketing (Altuntas Vural 2015)

Conventional marketing in the figure stands for the traditional marketing strategy that prioritizes profitability for organizations both in the short and in the long run. The means to this profitability is seen as customer satisfaction. Marketing mix is designed and revised in accordance with competitive considerations. Customer wants are at the focus of marketing effort regardless of a transactional or a relational approach. Despite the dominant economic perspective, considerations for environment or society are not inexistent; however, they are mostly at compliance level to laws and regulations.

Green marketing and societal marketing represent the marketing strategies and practices that consider environmental impact and societal impact, respectively. However, these are not independent concepts. Majority of negative environmental impact caused by marketing activity has societal consequences such as waste produced by excessive packaging, or dangerous chemicals used in products result in negative impact on human health. On the other hand, natural environment is not dependent on society; it is the society that depends on natural environment. Therefore, any environmental marketing effort that eliminates negative environmental impact of business activity will have positive consequences for the society as well.

Within this pillar, social marketing is also essential to make a change in behavior toward sustainability. Social marketing can be used to promote sustainable consumption and encourage

regulatory frameworks for environmentally sustainable production, consumption, and disposal. Social marketing can function as the strategic use of marketing tools for marketing sustainability.

Peattie (2001) states that although many efforts were made with respect to developing green products, targeting green customer segments, or improving the environmental performance of supply and distribution chains, the overall achievement in relation to sustainable development goals is not close to desired levels. He explains this situation with three main sustainability challenges for marketing. The first one is the futurity component of sustainable development that challenges marketing to justify why meeting today's customers' needs are more important than meeting future generations' needs. It is important to make goods and services available not only to current customers but the customers who belong to future generations as well. The second one is the equity challenge that underlines the high share of industrialized nations in overproduction and overconsumption and the related negative environmental impacts. The burden of industrialization is endured by less-industrialized nations, while the benefits of industrialization provided in terms of goods and services are not distributed equally among nations. Finally, the third one is about shifting the emphasis of marketing from wants to needs to achieve sustainable development.

These challenges and the inability of green marketing or societal marketing making it to mainstream marketing for almost 50 years are a

result of the continuous battle between the conventional economic perspective that welcomes these sustainability initiatives as long as they don't compromise the short- and long-term financial targets and even use them as a leverage to achieve these targets. Whenever there is a compromise requirement for sustainability, it comes rarely from the economic pillar. That is why Gordon et al. (2011) propose an alternative framework for sustainable marketing. According to this framework, sustainable marketing can be achieved by using the power of marketing through green marketing, social marketing, and critical marketing. While green marketing is used to design, develop, promote, and distribute environmentally friendly products and services, social marketing helps to create sustainable behavior change among consumers, producers, sellers, and regulatory authorities. But without a critical marketing approach, the changes to the existing system would remain only marginal. For a systemic change toward sustainability, the fundamental principles of marketing such as globalized economic development, increased consumption, or profitability need to be challenged in favor of quality of life in addition to quality of services and products, re-localized economic growth, and self-sufficiency based on renewable resources.

Summary

Sustainable marketing is a concept that is larger than green marketing or societal marketing. While including the objectives of both, sustainable marketing is an alternative to the well-established commercial marketing thought that prioritizes economic performance. It is not about producing and selling environmentally friendly products and services for earning more profit. It is not about introducing social responsibility campaigns for reputation marketing. As the early discussions on societal marketing pointed well, reduction or elimination of negative environmental and societal impacts of marketing will provide long-term profitability for businesses as they are dependent on the natural environment and the society to survive.

However, the fundamentals of conventional marketing need to be challenged to find alternative means for achieving long-term profitability. Systemic change is required to alter current structure of markets, commercial performance indicators, valuation of natural resources, and ecosystem services and approaches to production and consumption. Critical marketing theory could lead the way toward this systemic change and become a means for achieving a fundamental transformation toward sustainability in marketing.

view, keeping at its core the person's well-being. Material poverty shows itself when indispensable goods are lacking. Poverties different from the former can be found in very numerous situations of discomfort and dependence which, especially in the western world, are spreading at dizzying speed.

Moreover, by way of examining the dimensions that development should have, sustainable modernity is considering the trends which are showing in such a period where digitalization and the lack of relational goods represent the main features that tend to make the person, especially within businesses, less and less physically part of the productive process. In order to remedy these matters, the term “sustainable modernity” is suggested to give space to those contradictions that development involves. All this in order to contribute to building a more livable, fair, and beautiful economic system.

[Inclusive modernity](#); [Integral development](#); [Relationships development](#); [Social responsible development](#)

Definition

Sustainable modernity indicates the dimensions that development should have in order to be able to create better conditions of existence from a social, economic, and environmental point of

The Dimensions of Sustainable Modernity

Among the dimensions on which sustainable modernity unfolds (Rullani 2010), the first one concerns the integral development of people who are agents of social life and of businesses which instead mainly operate in the economics field. The word “integral” (Sorci 2007) includes the growth of professional expertise with reference to the work that they are actually carrying on, but also the immaterial aspects which characterize subjects, and therefore businesses as well, who require adequate spaces for reflecting, for thinking. We include, among these spaces, those areas concerning relationships (McIntyre 2009) and consequently the contribution to building relational goods (Gui 1996). This in that, in relational goods, relationships, and especially the interpersonal ones, is a good in itself.

Another dimension of sustainable modernity relates to inclusion and that is the capacity of all subjects, and therefore of businesses as well, of involving subjects with a disadvantage or a different ability in the economic-social process which concerns the production of goods and

services of all kinds. This process is really important in order to guarantee justice and fairness of treatment (Nussbaum 2006).

The third dimension concerns the danger of dissipated growth (Rullani 2010) which consists in destroying relational goods. This occurs by way of an erroneous interpretation of time subdivisions: work time, free time, time for family, and time for reflecting and thinking (Donati 2003). This danger takes place when harmony of the different facets of modernity disappears and too much importance is given to one of the outlined aspects. For example, work is solely considered important, or is it only free time?

This is all the more serious if certain limits, which are defined critical points, are crossed, so creating pathologies, like the use of mobile phones and/or computers that can be beneficial for development, or they may produce dependence and therefore contribute to diverting the subject from real life and everyday tasks. This limit-crossing may involve loss of meaning of his/her own activity and make bewilderment and desperation grow. The critical point represents a turning point where those goods (comfort), which we daily use – mobile phones, cars, computers, and so forth – change from positive goods into goods that create “damage” to ourselves and to society. Especially in western societies, we have already stepped amply over this critical line and, therefore, incorrect use generates social “uneasiness” instead of social “well-being” (Bruni and Zamagni 2016).

The fourth dimension is the ability to develop behaviors which tend toward gratuitousness (Bruni et al. 2008) and reciprocity (Bruni et al. 2008). By way of gratuitousness it is not meant that the various activities are carried on for free. Gratuitousness is based on the ability of subjects to carry on his/her own activity in order to make the subject that is beside him/her better, but also keeping the improvement of life quality of near and far people in mind and heart.

Reciprocity refers to the possibility of cooperation in building relationships that generate a bidirectional approach where your work/service does not always have the same quality or is not always of the same quantity of the work/service of

your counterpart. However, in this case as well, there are differences of intensity. That which is considered essential for sustainable modernity is the ability to cooperate in all cases with an objective that goes beyond contingency; rather, it opens up greater horizons of time and space.

The fifth dimension concerns reconsidering prize mechanisms which are excessively oriented toward meritocracy. These mechanisms are based on individual merit and, for the way in which they are outlined in the current state of the art, create inequalities because they are calculated on the final results instead of on behavior and process. Merit has been taken by capitalism as a veneer in order to make everything more efficient from the viewpoint of success, power, and money. However, “histories,” and therefore the starting points of each subject, are different as well as are their ways of acting. This means that certain features like patience, mildness, and ability to cooperate are not considered or rather “forgotten” (Bruni and Zamagni 2016). This triggers vicious circuits which widen inequality undermining sustainability at its very core (Baldarelli et al. 2017).

These dimensions can be considered both for individuals acting in the social environment and for economic operators like organizations and businesses.

Sustainable Modernity and Relational Goods: Some Notes

The characteristics can be summarized in the ability to create trust both in the environment, and inside the company, which is not simply the “legitimacy,” but it comes to seeking a true relationship with the environment, in all expressions, who become engines of both factors of production activities in the company, but also elements and essential guidance to the entire business activity.

The definition of company as a system of relations is, according to our point of view, a definition that needs to be clarified and in reality does not happen spontaneously because even within the company there are conflicting interests. So, on the one hand it is necessary that the undertaking takes account of how such behavior influences

economic variables, and on the other it is necessary to take into account that such behavior must be cultivated and built. This type of approach has a significant effect on the definition of the goals especially of the company (mission), the type of government (governance), and accountability.

Summary

The objective of having included this chapter is that of reflecting on certain aspects which are becoming more and more important in order to be able to solve some important issues, like that of poverty both material and of other kinds. The dimensions of sustainable modernity, which have been analyzed, are useful to base managers' decision processes to consider human and relationship variables as important as economic and financial ones.

Sustainable Performance

Elif Gulen Rady

Description

In 1987, the Brundtland commission's report, Our Common Future, called for a new model of global economic development (Brundtland report, 1987). This report offered what has become a

common definition of sustainable development as development that “meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED, 1987; p:41). Sustainable performance is a concept introduced after sustainable development and can be defined as a practice as the combination of its economic, social, and environmental performances (Chardine-Baumann & Botta-Genoulaz, 2014). Triple bottom line framework, introduced by Elkington (2004), suggested companies take a multidimensional perspective that integrates not only economic returns but also social and environmental aspects (Henao et al., 2019). According to this framework, companies can use all three aspects (economic, social, and environmental) as a foundation for building sustainable performance and measure performance against the three.

The literature on sustainable performance is growing; however until this point, there are two main conceptual streams observed in existing literature. The first view suggests that there are trade-offs among the three pillars of sustainability (economic, social, and environmental), where improving on one pillar can be detrimental to the others. The second view suggests that there is a positive relation among the pillars and improvement in one pillar can have a positive influence on the others (Henao et al., 2019).

Tools and Techniques to Achieve Sustainable Performance

Lean manufacturing has emerged as a dynamic learning process, which can guide companies to achieve positive economic outcome while using less resources and adding value to customers (Shah & Ward, 2007). There is growing body of literature on understanding the impact of lean manufacturing on the sustainable performance (Cherrafi et al., 2016; Hartini & Ciptomulyono, 2015; Martinez-Jurado & Moyano-Fuentes, 2014). The building blocks of lean manufacturing include several tools and techniques that have been practiced in Japan for years and include Kaizen, 5S, Total Quality Management (TQM), Value Stream Mapping (VSM), to mention a few

(Posajek, 2003). Companies have adopted these tools to achieve sustainable performance goals in their organizations. For instance, 5S technique that is one of the tools of lean manufacturing has been widely adopted by organizations since it brings stability and improvement in a continuous way (Randhawa & Ahuja, 2017). Osada (1991) introduced 5S concept, which can help companies build high quality products, reduce costs, and improve safety, availability rate, and product diversification. The key elements of 5S as defined by author are:

- Seiri – Organization
- Seiton – Orderliness
- Seiso – Cleanliness
- Seiketssu – Standardized cleanup
- Shitsuke – Discipline

The fifth element, Shitsuke (Discipline), is about making a habit of preserving established procedures and an important element to achieve sustained organizational performance. This means establishing a standard work across the organization so that every employee can utilize standard operating mechanisms to avoid surprises at the end. The existing literature on 5S proves that if adopted correctly, this tool can help companies achieve their sustainable performance goals (Bragança et al., 2013; Aziz et al., 2014; Putro, 2013).

Summary

Sustainability is a process where companies integrate their economic, social, and environmental objectives into their business values and strategies, and hence, it is a process rather than an end in itself (Székely & Knirsch, 2005). In today's competitive business environment, this means going one step further than just following the rules and regulations but also establishing a work environment and principles where all three aspects of sustainability (economic, social, environmental) can flourish. Székely and Knirsch (2005) argue that there are at least three critical success factors to achieve sustainable

performance. These factors are leadership and vision, flexibility to change, and openness through stakeholder engagement.

One of the key challenges regarding sustainable performance is building key performance indicators (KPI's) and eventually measuring the performance of the company against these KPI's. In today's world, companies' stakeholders are becoming more demanding and vocal on understanding sustainability information in addition to financial performance (Brown, 2000). Investors demand evidence of good corporate governance, customers demand information on footprints of the products, employees demand their workplaces to have corporate social responsibility practices, and governments demand companies follow the rules and regulations regarding sustainability (Keeble et al., 2003). This demanding stakeholder environment puts pressure on the companies to use indicators to measure sustainable performance both at a corporate level and at a functional or divisional level.

Sustainable Remediation

Daniela Lud
Faculty of Communication and Environment,
Rhine-Waal University of Applied Sciences,
Kamp-Lintfort, Germany

Definition

There are several definitions of the term Sustainable Remediation. In general remediation

of contaminated soil and groundwater refers to mitigation (reduction or control) or elimination of risks which are considered to be unacceptable to environmental receptors or human health. While remediation activities improve soil and groundwater quality locally, they can also have negative environmental effects. These effects can include impacts on site level as well as impact on a global scale, e.g., through CO₂ emissions during remediation. Introducing sustainability concepts into soil and groundwater remediation implies balancing the three interconnected aspects of sustainability: economy, environment, and society. Important definitions of Sustainable Remediation include the definition in an international standard document on Sustainable Remediation (ISO 2017; Nathanail et al. 2017) and definitions of practitioners' networks (Ellis and Hadley 2009; NICOLE 2010; SuRF-UK 2010).

Sustainable Remediation refers to “elimination and/or control of unacceptable risks in a safe and timely manner whilst optimizing the environmental, social and economic value of the work” (Nathanail et al. 2017).

The network for industrially contaminated land in Europe NICOLE (2010) defines Sustainable Remediation as “one that represents the best solution when considering environmental, social, and economic factors – as agreed by stakeholders.” The NICOLE roadmap underlines the importance of effective risk management as well as communication with stakeholders for successful integration of sustainability into the process of contaminated land management. According to Ellis and Hadley (2009), the term refers to measures where a “net benefit on human health and the environment is maximized through the judicious use of limited resources.”

Soil and Groundwater Remediation

Human activities such as industrial processes, energy production, or handling of waste can cause soil and groundwater contamination. Remediation of soil and groundwater contamination is performed to reduce risks of hazardous substances in soil and groundwater to human

health or environmental receptors. Further reasons to remediate are a change of ownership or site development (Vegter and Kasamas 2011). Targeted remediation removes or controls unacceptable risks to relevant receptors safely and within the given timeframe (Nathanail et al. 2017). Remediating a contaminated site completely to pre-impact status is usually not feasible, neither technically nor financially. Often remediation aims at rendering soil and groundwater quality fit for use. There are numerous techniques to remove contamination, to reduce contaminant concentration, or to prevent contact of receptors with the contamination. Contamination can be removed by simply digging out contaminated soil and landfilling the excavated material. More advanced techniques include reducing contaminant concentrations using microbial degradation or physical or chemical methods. Many of these techniques cause CO₂ emissions and use resources.

Early Concepts Integrating Sustainability into Soil and Groundwater Remediation

In the 1990s ideas of valuation of ecosystem services developed (Costanza et al. 1997). Ecosystem services are benefits provided by ecosystems to humans. Examples for ecosystem services are the provision of clean drinking water or degradation of contaminants by bacteria in the subsurface.

At the same time, there was a growing understanding of the extent of the soil and groundwater remediation task. In response to these developments, concepts to value clean soil and groundwater and to evaluate resource efficiency and environmental impact of soil remediation evolved. An early method is the risk reduction, environmental merit and cost (REC) method described by Beinat et al. (1997). This tool provides decision support to choose the remediation option with optimum balance between environmental merit, risk reduction, and costs based on value functions. Diamond et al. (1999) described a life cycle-based framework for soil remediation to facilitate the choice of

remediation options with optimum results for environmental impact and human health. This is an example of applying Life Cycle Thinking to soil and groundwater remediation. At the time integral approaches of contaminated land management evolved, considering environmental, economic, and social aspects. Risk-based land management (RBLM) was developed to balance requirements of adequate soil and groundwater quality with several other aspects. Examples for such aspects taken into account are environmental protection, financial aspects, and long-term care needed after remediation (Vegter et al. 2002). At the time sustainable remediation solutions were often seen in finding the optimum regarding several criteria such as fitness of the location for use, reduction of environmental risks, and minimized long-term obligations (e.g., control measures). In this context in situ remediation methods developed in the 1990s as resource efficient, more sustainable remediation approaches.

Development of Three Overlapping Concepts Integrating Sustainable and Green Remediation

In the early 2000s partly overlapping, yet different concepts of Sustainable Remediation developed: Green Remediation and Sustainable Remediation. The US Environmental Protection Agency (US EPA) defines Green Remediation as “The practice of considering all environmental effects of remedy implementation and incorporating options to maximize net environmental benefit of cleanup actions” (US EPA 2008). Green Remediation favors remediation methods with the highest environmental benefit (e.g., lower energy consumption and lower greenhouse gas (GHG) emissions). Green Remediation has a strong focus on environmental aspects such as materials and waste, land and ecosystems, water, air, and atmosphere. Similar to the concept of Sustainable Remediation, activities in Green Remediation are also embedded in a context of stakeholder involvement and resource efficiency. However the main focus of Green Remediation lies on methods with low climate impact. At the same time, the concept of Sustainable Remediation developed as an integral

approach (Ellis and Hadley 2009). This concept is centered on balancing impacts and benefits across the three pillars of sustainability. According to the authors, the remediation methods chosen should involve minimum energy consumption and minimum releases of contaminants to the environment. Also, methods mimicking natural processes should be preferred over chemical or physical measures. Furthermore Sustainable Remediation measures should facilitate reuse of land and methods eliminating contaminants, for example, by biological degradation to nontoxic substances. There is a strong focus on consensus-based stakeholder involvement and on finding a site-specific optimum solution (NICOLE 2010; SuRF-UK 2010). To integrate the Green Remediation concept into existing efforts to consider social and economic aspects, Interstate Technology and Regulatory Council (ITRC) published guidance for a combined Green and Sustainable Remediation approach (ITRC 2011). This latter concept represents the third of three partly overlapping concepts on eco-friendly or Sustainable Remediation. While

the focus of Green Remediation and Sustainable Remediation is different, there is considerable overlap between the concepts, especially with regard to implementation in practice (Hadley and Harclerode 2015).

Standardization of Sustainable Remediation Concept

Based upon earlier work of different authors and practitioners' groups in several countries (Bardos et al. 2013; NICOLE 2010), standardization efforts resulted in two relevant standards: the ASTM Standard Guide for Greener Cleanups (ASTM 2013) and the ISO standard on Soil Quality: Sustainable Remediation (ISO 2017; Nathanail et al. 2017). The ISO standard specifies terms and methods for the selection and assessment of remediation strategies. A timeline depicting important milestones of the development of sustainability concepts in soil and groundwater remediation is given in Figure 1.

Sustainable Remediation, Fig. 1 Timeline of the development of the concept of Sustainable Remediation (Martino et al. 2016; Smith 2019; Slenders et al. 2017). The representation differentiates between early approaches, approaches with a focus on environmental aspects and integral approaches covering three pillars of sustainability. The milestones shown are REC (Beinat et al. 1997), life-cycle approach applied to soil remediation (Diamond et al. 1999), RBLM (Vegter et al. 2002), Green

Remediation Tech Primer (US EPA 2008), SURF White Paper Sustainable Remediation (Ellis and Hadley 2009), Framework for Assessing the Sustainability of Soil and Groundwater Remediation (SuRF-UK 2010), NICOLE Roadmap to Sustainable Remediation (NICOLE 2010), Green and Sustainable Remediation: A Practical Framework (ITRC 2011), Standard Guide for Greener Cleanups (E2893–13) (ASTM 2013), and ISO 18504:2017 Soil Quality: Sustainable Remediation Standard (ISO 2017)

Bardos et al. (2011) emphasize that it is necessary and challenging to use an appropriate form of sustainability assessment to identify the approach which achieves the best balance. More recently special emphasis is given to the integration of the social aspect of sustainability into the remediation process (Harclerode et al. 2015). While a lot of work has been done to integrate the economic and environmental aspects, more work is needed to come to appropriate site-specific adaptation of indicators and metrics also for this aspect of sustainability.

Qualitative and Quantitative Metrics and Tools to Support Decision-Making and Contaminated Land Management

From the beginning, the emergence of the topic Sustainable Remediation was characterized by a strong awareness that sustainability of a remediation strategy needs to be proven (Bardos et al. 2011). In the concept of Sustainable Remediation, decision support for a sustainable choice plays a central role. Obviously this means that indicators and metrics are needed to be able to compare remediation strategies. In this context an indicator is a parameter which can be used to compare the sustainability of various remediation options. SuRF UK has set up a list of 15 headline categories, 5 headline categories for each aspect of sustainability (environmental, economic, and social). Examples for such headline categories are emissions to air or natural resources and waste (environmental), direct costs and benefits or employment (economic), and human health and safety (social) (Bardos et al. 2018; SuRF-UK 2010). These indicator categories can serve as a point of departure for choosing and agreeing on a relevant site specific set of indicators (NICOLE 2010; SuRF-UK 2010). A metric is a measure for an indicator (e.g., amount of CO₂ emitted as a metric for the headline category emissions to air). Metrics can reflect a single aspect of sustainability as well as a combination of two or three aspects (Butler et al. 2011). The metric is used to determine performance of remediation options.

An overview of different metrics and tools is given in Huysegoms and Cappuyns (2017) or

on the website of SURF (www.sustainablemediation.org). Tools include qualitative, semi-quantitative, and quantitative tools. Both from practitioners' and researchers' point of view, it seems important that the most simple way to compare remediation alternatives should be used (Nathanail et al. 2017). Smith and Kerrison (2013) evaluated several tools to rank sustainability of remedial options with regard to effort needed, practicability and data requirements. They found that for simple projects, simple sustainability assessment provides the same result as more complex assessment procedures. So it is possible to adapt the complexity of the assessment to the requirements of the project. Care should be taken that on the one hand all relevant impacts are covered by the selection of indicators and metrics, while on the other hand indicators and metrics are consistent and do not duplicate information (Bardos et al. 2018; Butler et al. 2011). To come to a good fit between stakeholders' needs and the chosen option, it is important to agree on relevant indicators with all stakeholders and balance impacts and benefits for all aspects of sustainability (NICOLE 2010). This way both assessment and communication with stakeholders can be targeted and at the same time relevant and complete. Some social indicator headlines are relatively straightforward to use, e.g., human health or safety at work. Others are more challenging to adapt to site-specific situations, e.g., when it comes to equity, neighborhoods, and community involvement. The concept of Sustainable Remediation is still evolving. In spite of all achievements of standardization, the actual challenge is to implement Sustainable Remediation site-specifically. It is a demanding task to translate standards and guidance documents into optimum solutions for local communities.

Outlook: Sustainable Remediation and Sustainable Development

Over the coming decades, a reduction of GHG emissions will be necessary. As soil formation is a very slow process, soil basically is a

nonrenewable resource. Therefore there will be an increasing need to use resources of land and soil fair and sustainably. In general, soil plays an important role in attaining the United Nations Sustainable Development Goals (SDGs) because soil plays a crucial role in the provision of ecosystem services (Blum 2016). Many SDGs are linked to soil functioning (Rodríguez and Payá Pérez 2018). This holds for SDG 2 on ending hunger and for SDG 6 on availability of water, because both SDGs rely on ecosystem services provided by soils. Soil sealing and soil contamination are two forms of anthropogenic impact on soils threatening sustainable development (Blum 2016). Both threats can be reduced by Sustainable Remediation as Sustainable Remediation can limit resource use and balance impacts and benefits of soil remediation across the three aspects of sustainability. Therefore it can be stated that a considerable proportion of the SDGs is linked to Sustainable Remediation. So, for example, SDG 13 (“take urgent action to combat climate change...”) and SDG 15 (“Protect, restore and promote sustainable use of terrestrial ecosystems...”) also require the functioning of soil ecosystems (Bardos et al. 2018; Keesstra et al. 2016). Sustainable Remediation can lessen land use conflicts, reduce the use of limited resources, abate human health risks, and improve the economic value of land. Therefore it can be assumed that future remediation projects need to be sustainable.

Summary

Sustainable Remediation means to integrate sustainability assessment into remediation and balancing benefits for environmental, social, and economic aspects. There are several definitions and concepts developed in parallel by standardization bodies and practitioners. The Green Remediation concept refers to efforts making remediation more environmentally friendly, the Sustainable Remediation concept puts emphasis on remediation options achieving the best balanced outcome regarding the three aspects of sustainability (environmental, economic, and

social), and the Green and Sustainable Remediation concept tries to integrate both concepts. A guided process of consensus forming among stakeholders on indicators and metrics can help to find optimum site-specific solutions for remediation of contaminated sites. Sustainable Remediation is linked to SDGs.

Effective rewards

Definitions

A sustainable rewards system means shaping and evaluating rewards systems within an organization to foster the integration of key stakeholder goals and creating mutual understanding and dialogue, in addition to analyzing the long-term effects of such action. The sustainable rewards approach stresses the role of people within the organization and underlines the importance of the creation of favorable conditions for further sustainable development of the organization and its employees. This harmonious development is considered over the long-term and concerns the so-called triple bottom line; that is, the application of solutions that are socially responsible, ecologically friendly, and economically valuable at the same time.

Introduction

Due to excessive exploitation of both natural and human resources, sustainability has become an important issue over the past decade (Ehnert 2008). Increasing awareness of the importance of sustainability has necessitated that organizations conduct business in such a way that human needs and aspirations achieve a balance with environmental, economic, and social concerns. Creating sustainable development through appropriate human resources practices and tools is one way in which employers can meet present and future needs (Renwick et al. 2012).

Today, practices that create sustainability are used in all functional areas of human resources management: recruitment and selection, training and development, and performance and rewards. Of these practices, employee rewards seems particularly important, in that it helps build employee well-being while supporting desired and ethical employee behaviors. Research and a review of the literature on the subject, however, indicate that rewards may have outcomes opposite of what was intended (Werbel and Balkin 2010; Transparency UK 2016). Inappropriate design of rewards systems or unethical behavior of employees may lead to abuses, and excessive pressure on results can lead to decisions and actions that harm the interests of some stakeholders. For example, a high financial bonus may lead a manager to undertake risky activities that have negative consequences on the natural environment or on the local community. Similarly, too low salaries may lead to negligence that affects the important interests of other stakeholders.

Hence, there is a need to pay special attention to sustainable rewards systems which create the material and social well-being of employees and support appropriate, balanced attitudes and behaviors of employees toward other stakeholders of the organization.

Definition of Sustainable Rewards Systems and Context

Sustainable human resources management (SHRM) is a relatively new area (Moxey 2016; Klimkiewicz and Beck-Krala 2015; Sahakiantz et al. 2015), although issues such as pay inequality or pay transparency connected with SHRM have been reflected in the literature for a long time. SHRM refers to human resources programs, procedures, and practices that lead to harmonious development. SHRM stresses the importance of employee development and improvement of organizational performance via economic, environmental, and societal outputs (Beck-Krala and Klimkiewicz 2018). In practice, SHRM focuses on achieving organizational goals while improving employee well-being through:

- Reducing stress at work and implementing a policy of equal treatment
- Developing a supportive work environment and work–life balance
- Building a culture that promotes high ethical and moral values: transparent communication, trust, cooperation, etc.
- Increasing employability levels through professional development
- Offering competitive total rewards packages (among them, development opportunities on both a professional and personal level) and an attractive level of remuneration (Docherty et al. 2002; Ehnert 2008; Beck-Krala and Klimkiewicz 2018)

A **sustainable rewards** system means shaping and evaluating rewards systems within an organization to foster the integration of key stakeholder goals and creating mutual understanding and dialogue, in addition to analyzing the long-term effects of such action (Beck-Krala and Klimkiewicz 2018, pp. 44–45). The sustainable rewards approach stresses the role of people within the organization and underlines the importance of the creation of favorable conditions for further sustainable development of the organization and its employees (Ehnert et al. 2014). This harmonious development is considered over the long term and concerns the so-called triple bottom line; that is, the application of solutions that are socially responsible, ecologically friendly, and economically valuable at the same time (Elkington 1998). According to this approach, a well-designed rewards system simultaneously meets the goals of the organization and the expectations of the main stakeholders – employees, managers, and shareholders – through motivating employees to adopt desirable behaviors and outstanding performance. Therefore, it focuses on a long-term perspective to develop organizational and main stakeholder well-being. Main stakeholders are owners, employees, managers, customers, suppliers, the natural environment, or local communities and other groups that may be affected by the company.

There is a scarcity of publications in the literature that address the subject of sustainable rewards systems (Linder and Mottis 2013;

Sahakiantis et al. 2015). Sustainable rewards systems can be examined in the context of two perspectives (Beck-Krala et al. 2019):

- How salary levels, incentives, employee benefits, and the work environment support CSR and sustainability and how these programs may influence employee decisions with CSR and sustainability implications
- How rewards encourage employees to take socially responsible and environmentally sustainable actions, which could include making charitable donations and volunteering to support community programs

The second perspective is often referred to as Corporate Social Performance (CSP), which means evaluating corporate performance in terms of the triple bottom line.

The Classification of Sustainable Rewards

Sustainable rewards systems include motivational programs which target three main areas in addition to incentives: economic, social, and environmental.

Figure 1 (below) shows the different orientation of rewards programs (Beck-Krala and Klimkiewicz 2018):

- Rewards programs oriented toward economic efficiency focus on the achievement of economic objectives and include bonus programs or rewards based on financial performance (targets). Measurement criteria used in such programs are usually quantitative (e.g., sales value, quantity of production).
- Rewards programs focused on building relationships with employees are strongly oriented toward the relationship with main stakeholders (e.g., needs of employees). These programs not only motivate toward achievement of financial goals but also improve employee well-being and increase employee and community safety. Examples of such programs are rewards programs based on competencies, cafeteria programs, and

Sustainable Rewards, Fig. 1 Different orientation of rewards programs. (Source: Based on Beck-Krala and Klimkiewicz 2018)

bonuses, including qualitative performance criteria, such as quality of service provided to customers and employee development.

- Environmental incentive programs or pro-environmental green incentive programs are primarily aimed at reducing the negative impact of the organization and its people on the environment (organizational footprint). These programs are aimed at strengthening and creating attitudes and behaviors that support pro-ecological activities. Examples include programs aimed at reducing pollution and reducing water and energy consumption in the workplace.
- Support programs are geared toward the achievement of social or environmental goals but do not have a direct link to financial motives. Examples include recognition-type awards for achieving social and environmental goals, such as employee volunteer programs or knowledge sharing.

Sustainable rewards systems cover programs from all three areas. Examples of these are incentive programs created with the use of a balanced scorecard that takes into account ecological,

social, and economic criteria in all areas of the scorecard – financial, customer, internal processes, and development. By selecting appropriate practices and incentive programs from different areas, organizations can diversify and balance the range of motivational solutions.

The Importance of Sustainable Rewards

Designing sustainable rewards has become particularly important because of many negative examples and abuse that have resulted from improper rewards practices (Werbel and Balkin 2010; Moxey 2016; Sahakiantz et al. 2015). Examples of large companies that lost their reputation or became bankrupt because of the unethical behavior of their employees who were motivated by abusive rewards programs – mostly short-term incentive programs – are widely commented upon and described in the media and in the literature [e.g., the case of Enron, BP, Volkswagen, Wells Fargo (UK Transparency 2016)]. Sustainable rewards needs to focus on both prevention of possible negative societal impacts of business

according to the rule “do no harm” (European Commission 2011) and evaluation of the possible negative impact of rewards on stakeholders. The most common cases where rewards may harm stakeholders are concerned with the violation of employee rights. Cases of inequality in pay and the large pay gap between men and women, child labor, too low wages, lack of insurance, etc. are some of the key aspects of rewards that harm employees. Sustainable rewards means avoiding *over-exploitation* of employees (Ehnert 2008) that causes, in the long term, work-related stress, work–family conflicts, and even health problems and employee burnout. Thus, shaping sustainable rewards systems, apart from their effectiveness, focuses on creating a policy of equal opportunities, offering fair salaries, and a healthy and safe work environment which might be extended to work–life programs. Sustainable rewards systems are most often present in socially responsible organizations or those characterized by a strong culture that promotes important values, such as safety, trust, innovation, open communication, etc. This requires, for example, ensuring compliance of the rewards systems with applicable domestic or international law. In some countries, apart from legal requirements, it is recommended that accepted ethical standards and social norms, as well as traditions of the countries in question, be respected or maintained (Scott and Beck-Krala 2019). Furthermore, poorly designed rewards programs, particularly incentives, may result in counterproductive employee work behavior, such as aggressive risk-taking, mis-selling, fraud, destruction, and misuse of organizational property (Werbel and Balkin 2010). Such misbehaviors may have detrimental consequences for other stakeholders and the organization itself (Spector et al. 2006). In order to avoid any harm that the rewards system may create, organizations need to provide regular risk assessment and monitoring to deter unethical employee behavior.

For employees, rewards systems are of great importance when choosing an employer and place of work. Sustainable rewards gives employees the message that the law will be respected and that they will have more attractive rewards and a supportive work environment that will allow them to

balance work with personal and family responsibilities. Furthermore, for younger generations, such as Millennials currently entering the labor market, socially responsible involvement of the employer in activities that are important and beneficial for the community and the natural environment are of key importance when selecting the workplace. Employees are also looking for a sense of purpose and want the opportunity to realize their personal values in the workplace. Therefore, in the face of the scarcity of the pool of talent that plays a significant role for every employer, sustainable rewards can help in promoting socially responsible attitudes of employees by rewarding desirable ethical behaviors (Sahakiantz et al. 2015; Linder and Mottis 2013). Financing volunteer work that supports the local environment or community is particularly popular and has great value for employees.

The Characteristic of Sustainable Rewards

Sustainable rewards programs are characterized by some important principles. These principles arise from current challenges organizations are facing and are consistent with their core values and societal norms. Therefore, sustainable rewards should be as follows (Beck-Krala et al. 2019):

- Legal and Liveable: rewards must comply with labor standards of the country in which the organization is operating, as some global companies have been accused of being irresponsible to their employees by providing poor working conditions, abusing child labor laws, forcing overtime, or abusing human rights (Crane et al. 2014, p. 229)
- Safe: providing safe and healthy working conditions and reducing workplace-related injuries and illnesses
- Equitable: consistent with societal norms and not encouraging employees to participate in unethical or illegal behavior
- Transparent: opens the rewards system to scrutiny by all stakeholders and may demonstrate to employees that their pay is fair, at least

within the context of company policies and government regulations

- Economically Sustainable: takes into account not only the economic rationality and cost effectiveness but also is based on the assumption that economic value depends on noneconomic factors, such as employee engagement and willingness to perform given tasks
- Creates employee well-being in a long-term perspective: rewards strategies rely on both financial and nonfinancial rewards and help build a supportive environment and development opportunities for employees (Total Rewards approach)
- Does not harm other stakeholders: which may happen when rewards programs are poorly designed (most often short-term incentives programs) and may lead to unethical employee behavior or employee misconduct that can be directed against both the organization and other stakeholders (Werbel and Balkin 2010; Spector et al. 2006).

Evaluation as an Integral Part of Sustainable Rewards

Monitoring the effectiveness of rewards programs is essential (Beck-Krala and Klimkiewicz 2018), particularly because organizations face extensive competition for talent while working to optimize costs. The pressure to meet targets and the need to win business may lead to shortcuts that result in various forms of corrupt and unethical behavior. Therefore, employers must be aware of the risks connected with rewards and the need to evaluate the effectiveness of rewards systems. Sustainable rewards requires a comprehensive evaluation methodology that includes both shareholder and stakeholder views in which the evaluation process is based on both hard facts and quantitative measures as well as qualitative measures (Klimkiewicz and Beck-Krala 2015). Therefore, effective sustainable rewards systems will focus on both economic efficiency (profit oriented) and effectiveness (goal oriented) and will also be responsible to their main stakeholders (Beck-Krala 2018).

The first dimension of effective, sustainable rewards – economic efficiency – requires quantifying the total cost of the rewards system; this often also includes return on investment. The second dimension evaluates if the organization has achieved the main goals of the rewards system, such as attracting and retaining talent. Then, the responsibility dimension, a part of sustainable rewards that means the ethical aspects of rewards effectiveness (such as social justice and long-term impact of the system according to the rule “do no harm”) are extremely important and should be considered in the evaluation methodology. In the first dimension, various economic measures may be used; for example, the return on investment in compensation, total cost of the rewards package, etc. In the second dimension, achievement of the rewards system’s goals are assessed and such measures as turnover rate, absenteeism, external attractiveness of the total reward, etc., may be used. Finally, the responsibility dimension may use such measures as employee satisfaction with the rewards, customer satisfaction with the service provided, number of employee accidents at work, total number of employees, and work hours spent on volunteering at sustainable projects.

The literature offers some examples of comprehensive models for analyzing the effectiveness of rewards systems. The following criteria may be present:

- Philosophy of the system and its convergence with the firm’s strategy
- Compliance of the system with formal regulations
- External competitiveness of the total compensation system
- Cost effectiveness of the payroll (and return on investment from the compensation)
- Satisfaction of the main stakeholders (e.g., employee satisfaction) with the system

Within these five criteria, employers can analyze areas of the rewards system that are most important to the organization. For example, the analysis may include the main components of the rewards package: financial compensation, non-financial compensation, growth opportunities,

and a safe and healthy working environment. Apart from the total rewards package, the process of distribution, transparency of the system, and other crucial aspects of the rewards process need to be assessed.

Sustainable Rewards in Practice: Some Examples

Many companies are just beginning to adopt sustainable practices; many other organizations, however, have already established a balanced scorecard approach which identifies and rewards the skills and behaviors needed to execute corporate strategy in terms of sustainability. There have been many recent instances of companies that have integrated sustainability metrics into performance assessment and compensation for executives, senior management, and even other employees (WBSCD report).

According to the research published by the World Business Council for Sustainable Development (www.wbscd.org) in Europe, 29% of the largest companies include environmental, social, and governance (ESG) factors in their executive remuneration policies (WSBCD report). The Dutch Association of Investors for Sustainable Development (VBDO) called on Dutch companies to base at least 60% of their remuneration on long-term goals and at least one third on sustainable targets. There are many companies that have linked executive pay to sustainable performance measures, such as SC Johnson, which linked executive rewards with the company's *Greenlist* program for product stewardship and reduction in use of hazardous chemicals. Others, such as Evonik (German chemical company) have linked performance measures to the bottom line of social, economic, and environmental aspects that are fully integrated with HR objectives (WBSCD report). Some companies, such as Shell, DSM, NovoNordisk, or Natura, have the balanced scorecard that is linked to their strategic plan and includes sustainable Key Performance Indicators (KPIs) (which again concern environmental, social, and economic measures). Other companies, such as Siemens, may link sustainable

metrics with performance evaluation, where senior managers are rewarded for promoting a culture of integrity. Some companies link sustainability to annual bonuses. For example, Akzo Nobel (Dutch chemical company) rewards their senior managers for sustainable performance based on the Dow Jones Sustainability Index (50% of their long-term bonus plan is tied to the company position). Finally, there are also companies that see the power of nonfinancial incentives and recognition in promoting employee sustainable behavior and innovations, e.g., giving employees the opportunity to realize pro-ecological projects during work time, encouraging employees to engage in charity for the local community, employer-sponsored charity programs in which employees participate. For example, in Areva (French energy company) employees are rewarded for best projects on sustainable development by the international experts panel with the biannual Areva Sustainable Development Award.

Key Points

In the area of sustainable development which drives long-term value creation, employers are beginning to understand how social and environmental issues matter to the business. More and more employers are aligning rewards and remuneration systems more closely with long-term value creation by integrating environmental, social, and ethical factors into rewards programs. This approach is called *sustainable rewards*. The basic assumption in sustainable development in business is that, in the long-term, shareholder value and stakeholder value can be aligned. Sustainable rewards focuses on a long-term perspective to provide harmonious development of the organization and its main stakeholders (mainly employees). This harmonious development is considered in the triple bottom line, which means that the rewards system (rewards strategy, programs, and tools) are simultaneously socially responsible, ecologically friendly, and economically valuable. Sustainable rewards uses a mix of incentives that support long-term sustainability and success of the

company (development and profitability of the organization) and its main stakeholders (e.g., employee well-being, customer satisfaction, the well-being of local society, care and preservation of the environment in the region, etc.). Such rewards programs are linked not only to economic (financial) targets, such as quantifiable and measureable outputs, but also to sustainable measures – social, environmental, and ethical – which are more qualitative in nature, such as safety, health, satisfaction, etc.

Summary and Conclusions

Two important elements of sustainable rewards are risk management and a comprehensive process of evaluation of the rewards effectiveness which may include the impact (both positive and negative) the system has on stakeholders of the organization in a long-term perspective. Employee rewards are powerful tools to drive performance on sustainability issues, such as energy efficiency, ethics, or innovation. By providing sustainable rewards, employers communicate that the company is serious about sustainability commitments. Research indicates that organizations in which sustainability and CSR are a central part of the managerial culture are more attractive to potential employees (Jones and Willness 2013). In this context, sustainable rewards can help organizations attract and retain talent by providing a competitive edge and also build a culture that creates employee awareness and responsibility for the business. This helps meet the requirements of the social contract expected between employer and employees – to be seen as responsible in relation to local and national norms, laws, expectations about pay, benefits, working conditions, security employment, health, etc.

When implementing sustainable rewards, the company first needs to create an open and ethical culture which encourages employees to adopt socially responsible behaviors (in accordance with social norms) and challenges targets or managerial decisions that may be dysfunctional. This may be reinforced by strong management values and alignment of business objectives with organizational

values. Incorporating and monitoring sustainable rewards is an educational process for both employees and employers. Employers and employees are at the beginning of this sustainable and long-term journey, and it is important for all of us.

Definition

Sustainable sports stadiums are sports facilities that are built and maintained for the purpose of housing competitive sporting events, and which operate in a manner that is consistent with socially responsible standards, including the ecological, economic, and social interests of society overall. To determine whether a given sports stadium meets the standard for being sustainable, one would need to consider at least five attributes of

the stadium construction: land sustainability; natural resource sustainability; economic sustainability; labor sustainability; and sustainability of community interest. Land sustainability addresses whether the building of a sports facility makes reasonable use of the available land given reasonably available opportunity costs to building a stadium on a given piece of land. Natural resource sustainability assesses whether a sports stadium does a reasonable job of conserving natural resources such as an energy and protecting the long-term sustainability of the broader environment. Economic sustainability relates to the efficient use of taxpayer funds to build a sports stadium, including whether the stadium remains operable and in-use for a reasonable period of time after its initial construction. Labor sustainability relates to whether there is socially acceptable compensation provided to both the labor force who build a sports stadium and the labor force who provide the entertainment housed within the stadium. Finally, sustainability of community interest relates to the likelihood that consumers of entertainment housed in a particular sports stadium will remain interested in attending events featuring that form of entertainment for a sufficient time period to make the building of that sports stadium viable.

Introduction

The global sports industry is valued at more than half a trillion dollar per year, making it a meaningful source of worldwide entertainment and employment revenue (Sanawane 2022). As an industry, commercial sports thrive on athletes competing against one another to prove themselves bigger, faster, and stronger than the competition. Rivalries emerge between countries, nations, and regional teams. For the most part, these rivalries are societally healthy.

As a by-product of the unique competitive spirit of organized sports, however, public and public parties regularly hire architects, who compete to build the most physically impressive structures to host organized sports. While the competition to build modern sports facilities is often innocuous, there may emerge important

issues of sustainability when the construction of a new sports stadium is commissioned.

Land Sustainability

Land sustainability is one important matter to consider when assessing the virtue of building a new sports stadium. Land is a finite resource (Peters 2010). Thus, when land is expended to build a new sports facility, there is the “opportunity cost” of using the land for other purposes (Wolla 2017). The finite nature of land is especially pronounced in large cities, where the building of sports facilities may mean an opportunity cost in terms of building hospitals, low-income housing structures, or even public works projects (“Shortage of Land” n.d.). Stadium building also might mean the loss of important community green spaces such as parks and nature preserves in certain communities.

While in most cases building new sports facilities does not overly deplete the supply of land, there are instances in which using land to build sports facilities may become controversial. For example, there theoretically could be instances where proposals to build new sports facilities compromise existing parks, wildlife preserves, or other green spaces. This would be a matter of important public concern. In addition, where a federal or state government uses its eminent domain powers to take land for the building of a sports stadium, some legal scholars argue that doing so may infringe on liberty interests (Birch 2012).

Natural Resource Sustainability

Beyond questions of how to allocate finite land, conserving natural resources is another important issue that may affect the decision of whether to build a sports facility (McHale 2019). In terms of environmental friendliness, sports facilities, much like all other forms of construction, vary in terms of their performance (McHale 2019). Stadiums that are built in a more environmentally friendly manner make efforts to conserve finite natural resources by adopting techniques such as

rainwater harvesting and recycling, as well as by using solar and wind power wherever feasible (“Website for Cascadia Sport” [n.d.](#)). They also make use of recyclable and/or recycled materials (“Website for Cascadia Sport” [n.d.](#)).

There are a number of recent sports facilities that have received praise for their attention to environmental sustainability (“The Five Most Sustainable Sports Stadiums in the World” [2018](#)). For example, the ArenA in Amsterdam, Netherlands, uses more than 4,200 solar panels and a wind turbine to produce its energy (“The Five Most Sustainable Sports Stadiums in the World” [2018](#)). Similarly, Levi’s Stadium in San Francisco, California, includes more than 1,000 solar elements including solar-powered pedestrian bridges. (“The Five Most Sustainable Sports Stadiums in the World” [2018](#)). And, Mercedes-Benz Stadium, which is home to the NFL’s Atlanta Falcons, became the first professional sports stadium to earn a platinum Leadership in Energy & Environmental Design (LEED) certificate based on its numerous energy-efficient and renewable energy projects including a storm-water management system and a pedestrian-friendly walking path leading to the stadium itself (“The Five Most Sustainable Sports Stadiums in the World” [2018](#)).

Yet not all new sports facilities meet the ideal standards for environmental friendliness. According to one recent article, the Dallas Cowboys’ new stadium “uses up to 750 megawatts (mW) of electricity during peak times . . . which is enough to power the entire city of Santa Monica” (McHale [2019](#), p. 128). Meanwhile, “[i]n one month . . . the 2014 World Cup in Brazil generated 2.7 million tons of carbon dioxide (CO₂)” (McHale [2019](#), p. 129). While technology exists to build environmentally friendlier sports facilities than the ones built in Dallas as Brazil, among other places, some of the reasons why some private and public entities may continue to build sports facilities that fail to meet the highest level of environmental standards include the lack of legal obligation to meet higher standards, failure to align the costs and benefits of investing in sustainable energy, and the belief by some architects that environmental friendliness may detract from the beauty of their stadium design.

Economic Sustainability

Issues of economic sustainability are also pertinent to the building of sports facilities, especially when the facilities are constructed with public funds. While municipalities compete for the opportunity to host high-profile sporting events such as the Olympic Games or the World Cup, most municipalities lose money from hosting these events, despite gaining intangible benefits such as civic pride (Lisa [2022](#)). Because public funds are finite, economic resources that are spent on building public sports facilities to host large national or international events, again, yield opportunity costs in terms of alternative spending opportunities (Wolla [2017](#)).

There are, of course, a select few sports facilities that have remained operational and popular with fans for a long time period – perhaps providing a sense of “best practices” in terms of economically sustainable sports construction. Perhaps most notably, the Melbourne Cricket Grounds in Melbourne, Australia, was first built in 1854, and it remains operational to this day as the home to professional cricket, Australian football, and a wide range of other high-profile sporting events (Smith [2021](#)). Although the Melbourne Cricket Grounds has undergone some expensive renovations over the years including the building of the North Stand at a cost of \$460 million AUD in 2006, the cost of these periodic repairs is likely far lower than would have been a total rebuild (Smith [2021](#)).

In the United States, there are also a number of iconic facilities that have enjoyed more than 100 year lifespans. Franklin Field in Philadelphia, PA, which was once the home to the NFL’s Eagles and remains the longstanding home to the University of Pennsylvania’s football team, has remained operational since 1895 (Kries [n.d.](#)). Another Ivy League football stadium, Harvard Stadium, has remained operational since 1902 (Kries [n.d.](#)). Meanwhile, Major League Baseball’s Boston Red Sox and Chicago Cubs have played in their iconic home stadiums, Fenway Park and Wrigley Field, since 1912 and 1914, respectively (Kries [n.d.](#)).

On the other end of the spectrum, however, there have been sports facilities built in recent decades with public money that have ceased to serve their intended purpose within one

generation. While the International Olympic Committee purports that “85 per cent of all permanent Olympic venues since 1896 remain in use” (International Olympic Committee 2022), reasonable minds may disagree as to how much use of a stadium is needed for it to be perceived as economically viable. As an example of one stadium that remains technically in use but questionably utilized, Turner Field, which was commissioned by the City of Atlanta in 1990 to serve as the centerpiece to the Summer Olympics in 1996, became home to Major League Baseball’s Atlanta Braves before becoming deemed obsolete by the MLB team just 21 years later in 2017 (“Braves Moving to Cobb County in 2017” 2013). Turner Field has since been reconfigured for use as a football field for Georgia State University (Kahn 2017). But, with its present usage limited to just a six-game home college football season, one could reasonably question whether Turner Field was ever worth nearly the amount of money spent to build it.

Labor Sustainability

Adopting a broad definition of sustainability, “labor sustainability” in terms of reasonable worker protections is yet another area of concern related to building sports stadiums (Pagnattaro 2013). When sports facilities are constructed for massive events such as the Olympic Games or the World Cup, the finding of a sufficient short-term workforce to aid in the construction may be challenging. Ensuring that the workers who provide labor for these projects do so of their own volition is necessary, but not always followed. In building facilities for the 2022 FIFA World Cup, the nation of Qatar purportedly employed migrant laborers of African and South Asian descent to perform dangerous work for low pay; this has come under scrutiny for what some have described as “forced labor or other forms of modern slavery” (“Qatar World Cup’s Labor Abuse Amounts to ‘Modern Slavery,’ New Report Says” 2022). If the accusations are true, they present substantial concerns about stadium construction in conjunction with the World Cup.

Even in countries typically perceived as more progressive in terms of their labor rights, concerns have likewise emerged about the use of labor in preparing to host global sporting events. In Australia, some have criticized the purported use of incarcerated Aborigines from the Bathurst Prison in New South Wales to make artifacts and paintings for the 2000 Summer Olympics in Sydney, Australia, while receiving just \$12 AUD per week in pay (Syron 1999). In the United States, recent labor concerns have emerged where the construction workforce does not enjoy a legal right to universal healthcare, even despite the health dangers that may underlie certain forms of construction (Nuwer 2022). Moreover, college football players and basketball players in the United States, despite generating huge revenues for their schools while competing in many of the most luxurious facilities, are denied a free-market wage and other worker benefits based on the so-called NCAA Principle of Amateurism, which keeps the wealth of college sports in the hands of a select few coaches and administrators (Edelman 2013).

Taylor Branch, who is a Pulitzer Prize-winning author and expert on the US Civil Rights era, describes the NCAA system as one where “corporations and universities enrich themselves on the backs and uncompensated young men” and there is an “unmistakable whiff of the plantation” (Branch 2011). Branch is not altogether wrong.

Sustainability of Community Interest

Finally, the ongoing building of new sports stadiums leads to inevitable questions as to whether fan interest in sport, in itself, is even sustainable. Despite the famous saying from the 1989 hit movie *Field of Dreams* that “if you build it, they will come,” it seems somewhat presumptuous to simply declare that current levels of interest in attending commercial sporting events will sustain indefinitely. When considering the full scope of human life on Earth, the period of highly commercialized sports represents only a modicum of time within human existence. The modern Olympic Games date back only to 1896

(Sternfeld 2012). Professional baseball, cricket, and soccer trace their roots to only slightly earlier.

There are a number of existential threats to the future viability of sports stadiums as a commons for consumers to observe sports. The COVID-19 pandemic that struck in March 2020 called into question for some sports fans the safety of observing sporting events live, in the closed-in quarters of sports facilities, especially those with closed roofs (Edelman et al. 2021). Similarly, advancements in television, Internet, and Virtual Reality technologies present emerging ways for the consuming public to share the common experience of viewing sport without being in the same physical space via the stadium (“How Virtual Reality Can Deliver a Stadium Experience for Sports Fans in a Post-COVID-19 World” 2023). A 2022 *Virgin Media* survey found that nearly half of all football (soccer) fans would prefer to watch a match from their own couch than from within a stadium (Singh 2022).

Summary

The desire to be part of a shared communities continues to draw sports fans, and especially those with economic means, to attending live sporting events. Yet, for all the virtues of the live watching of competitive sports, the persistent building (and rebuilding) of sports facilities produces important societal questions in terms of sustainability. Federal and local laws, as well as international treaties and compacts, play a role in ensuring that future builders of sports facilities adopt environmentally sustainable and socially conscious practices when building new sports facilities. Nonetheless, the often-intense competition to secure the rights to sports teams and events may work against imposing laws to ensure the building of only sustainable sports facilities. As a result, certain practical challenges are likely to persist in promoting the building of sustainable sports stadiums.

Sustainable Stakeholder Dialogue

Rossella Leopizzi

Ionic Department in Legal and Economic System of Mediterranean: Society, Environment, Culture, University of Bari Aldo Moro, Taranto, Italy

Synonyms

Important stakeholders; Influencing stakeholders; Relevant stakeholders

Definition

A primary stakeholder group is one without whose continuing participation the corporation

cannot survive as a going concern. Primary stakeholder groups typically are comprised of shareholders and investors, employees, customers, and suppliers, together with what is defined as the public stakeholder group: the governments and communities that provide infrastructures and markets, whose law and regulations must be obeyed, and to whom taxes and other obligations may be due. There is a high level of interdependence between the corporation and its primary stakeholders. If any primary stakeholder group as customers or suppliers becomes dissatisfied and withdraws from the corporate system, in whole or in part, the corporation will be seriously damaged or unable to continue as a going concern.

This definition comes from the classification made by Clarkson in 1995 between primary stakeholders and secondary stakeholders, according to the formal relationship with the company.

Key Issues

Freeman, generally known as the founder of the Stakeholder theory thanks to his work “Strategic Management: A Stakeholder approach” (1984), considered in his model the company at the center of many interactions between stakeholders.

In the theoretical context of stakeholder theory, different stakeholder groups interact with company.

Stakeholders are defined as persons or groups that have, or claim, ownership, rights, or interests in a corporation and in its activities, past, present, or future. Stakeholders with similar interests, claims, or rights can be classified as belonging to the same group: employees, shareholders, customers, and so on (Clarkson 1995).

In literature, however, there are many definitions of stakeholders (Mitchell et al. 1997), all of which share their roots in the definition from Freeman (1984): “Any group or individual who can affect or is affected by the achievement of the organization’s objectives.”

Literature offers different proposals to classify stakeholders by their respective level of importance, as resumed in the following table by Mainardes et al. (2012) (Table 1).

Sustainable Stakeholder Dialogue, Table 1 Stakeholder classification typologies

Authors	Classification/criteria used
Goodpaster (1991)	The strategic and the moral stakeholder
Savage et al. (1991)	Stakeholder's potential powers to threaten or cooperate with the organization
Clarkson (1995)	The primary (with formal relationships) and the secondary (without formal relationships)
Mitchell et al. (1997)	Power, legitimacy, and urgency
Rowley (1997)	Network density and the centrality of the organization focus
Scholes and Clutterbuck (1998)	Power of influence, impact on the organization, and affinity with organizational objectives
Kamann (2007)	Power and the level of interest
Fassin (2009)	Classical stakeholders, stakewatchers, stakekeepers

Mainardes et al. (2011)

In particular, Clarkson (1995) was the first to divide stakeholders into two groups: primary and secondary stakeholders.

According to Clarkson (1995), the primary stakeholders were those that have formal or official contractual relationships with the company, such as clients, suppliers, employees, shareholders, among others, and the secondary ones are those not holding such contracts, such as governments and the local community, for example. In this way, a company is conceived of as a network of explicit and implicit relationships spanning both the internal and external environments. Furthermore, with the advance of stakeholder theory, greater interest began to be shown in these distinct interest groups and not only company shareholders or owners (Laffont and Martimort 1997; Argandona 1998; Gibson 2000; Delmar and Shane 2006; Wang et al. 2008; Forray and Goodnight 2010; Hirsch and Morris 2010).

From this perspective, the corporation itself can be defined as a system of primary stakeholder groups, a complex set of relationships between

and among interest groups with different rights, objectives, expectations, and responsibilities.

The corporation success depends on the managers ability to create satisfaction for each stakeholder group, so that each group continues as a part of the corporation's stakeholders system.

According to the same classification of Clarkson (1995), secondary stakeholder are defined as those who influence of affect, or are influenced or affected by, the corporation, but they are not engaged in transactions with the corporation and are not essential for its survival. They have the capacity to mobilize public opinion in favor of or in opposition to, a corporation's performance. Even if they are not essential for survival, such groups can cause significant damage to a corporation.

The stakeholders, being among the main protagonists of corporate life, feel the need to be integrated and contribute to improving the company in which they are involved. Therefore, stakeholder engagement (SE) becomes a composite process that includes more methods of interaction consultation, communication, exchange, and dialogue between the company and its stakeholders. Greenwood (2007) identifies SE as the set of procedures that an organization develops to involve stakeholders in organizational activity, in order to create a system of cooperation (Phillips 1997).

Stakeholder theory scholars have tried to classify the relational models between organizations and stakeholders by assuming a gradual growth of stakeholder involvement and participation. First, the organization identifies and maps its stakeholders, if possible distinguishing between primary parties (those who are strategic in the middle to long term) and secondary parties (stakeholders that do not affect its sustainability) (Clarkson 1995). Second, it tries to manage stakeholders' expectations and the claims they support in accordance with their salience (Mitchell et al. 1997), while also balancing these various positions through a process of stakeholder management (O'Dwyer 2005). In the last step, organizations try to engage primary stakeholders in decision-making processes, making them participants in organization management and governance, sharing information, dialoguing, and

creating a model of mutual responsibility. The stakeholder engagement phase, unlike the stakeholder mapping and management phase, “creates a dynamic context of interaction, mutual respect, dialogue and change, not a unilateral management of stakeholders” (Andriof et al. 2002). As a result, the main feature of stakeholder engagement is not to encourage the mere involvement of stakeholders to “mitigate” or manage their expectations, but to create a network of mutual responsibility.

Stakeholder engagement is a milestone corporate social responsibility (CSR) policy because it allows one party (the organization) to interact with another (the stakeholder) in a two-way dialogue in which the engager and engaged mutually learn from such contacts, deeply revising their expectations and preconceptions. In this sense, stakeholder engagement is a powerful tool of dialogic communication and accounting that offers interactive mutual learning processes that are capable of promoting transformative action and social change. According to Unerman and Bennett (2004), three key problems are associated with stakeholder engagement initiatives: identifying and reaching a wide range of stakeholders; determining a consensus set of stakeholder expectations from a range of potentially mutually exclusive views held by different stakeholders; and engaging them in an authentic two-way conversation. This does not exclude the possibility for stakeholders to communicate with each other without the intermediation of corporations that hold “legitimate interests” (Evan and Freeman 1988; Friedman and Miles 2006).

Future Directions

Undoubtedly, nowadays, stakeholder theory could not develop enough understanding of the heterogeneity of stakeholder claims and interests in focal firms. More importantly, the common or generic categories of stakeholders – for example, suppliers, customers, shareholders – are considered inadequate because they do not offer a realistic portrait of the stakeholders that interact with firms. Additionally, stakeholder theory is silent on

what occurs when these generic categories break-down (Freeman et al. 2010). This silence limits the ability of stakeholder theory to prioritize stakeholder claims. Building on stakeholder salience, Perrault (2017) proposed “status” as an attribute that explains how managers assign salience to various stakeholders and attempts to define how stakeholder claims are prioritized based on their status. Perhaps the first step for future research on this connection would be to empirically examine Perrault’s (2017) proposition of the relevance of status with stakeholder salience and other salience attributes, for example, power and legitimacy. Knowing how status translates into power and how stakeholders possessing different levels of status push their claims on focal firms should provide important knowledge for this field. Within the broader premises of the stakeholder theory examining the associations between status and power and between status and legitimacy would be helpful to understanding negative, additive, subsuming, and synergistic results.

Previous research has suggested that, apart from the originally proposed attributes of salience (Mitchell et al. 1997), proximity (Driscoll and Starik 2004), frequency of contact (Luoma-aho 2005), status and organization (as discussed above) also determine stakeholder salience. The attribute of proximity is relevant to modern organizational forms and to not-for-profit organizations because they build more on networks and coalitions (Yaziji and Doh 2009). Khurram et al. (2019) believe that there is a need to empirically examine the proximity and frequency of contact to be attributes of stakeholder salience. Moreover, a detailed effort should also be directed toward untangling these attributes and drawing conceptual boundaries that differentiate between the two.

Nowadays, a stronger general equilibrium analysis that better incorporates dynamic aspects of the stakeholder salience model is necessary. Future research should investigate the salience and importance of stakeholders considering the dynamic relationship between a company and its stakeholders, also in the light of the greater and greater importance given to digitalization.

Sustainable supply chain

Definition

Sustainable supply chain management involves integrating environmentally, socially, and financially viable practices into the comprehensive supply chain lifecycle, beginning with product design and development to material selection, manufacturing, packaging, transportation, consumption, return, and disposal. Such management and practices can help companies not only reducing their total carbon footprint but also in optimizing their end-to-end operations to achieve more significant cost savings resulting in profitability.

Why a “Sustainable Supply Chain”?

Any organization’s supply chain must operate beyond maintaining efficiency and profitability benchmarks by delivering improved environmental and social performance within a financially viable operation. This has a far superior impact on the environment than any other part of an organization’s operations. Organizations must

address several priorities in this domain including environmental stewardship, conservation of resources, carbon footprint reduction, financial savings and viability, and social responsibility.

Gary Hirshberg, President and CEO of *Stonyfield Farms*, best epitomizes the need for sustainable supply chains, when he said:

Even though we were the first manufacturer in America to offset 100% of the CO₂ emissions from our manufacturing plants, these incredible off-sets amounted to a rounding error in terms of our total carbon footprint. We realized that our supply chain – what is coming in and going out of our plant – represents 80% to 90% of our total carbon footprint. So, despite the great things that we did in our plant, unless we tackled our supply chain’s carbon footprint, we were nowhere.

According to the *Sustainable Supply Chain Foundation* (sustainable-scf.org), even though companies and consumers focus on the sustainable profile of a product and consider the sourcing and recyclability of products, there is a greater need to illuminate and understand the sustainability issues related to the transportation and distribution. Beyond the discernible benefits of reducing overall carbon footprint, and reducing energy and resource consumption, there are several other tangible reasons why companies should care about the sustainability in their supply chains, including:

- (a) Better bottom line – research and practice have demonstrated a clear, positive link between sustainability and financial outcomes.
- (b) Consumers and companies recognize the importance of green and social practices throughout the production process, and this, in turn, drives increased sales and share valuation.
- (c) Governmental initiatives around the world provide tax and investment incentives to firms that employ sustainable practices. In many regions around the globe, it is mandated by law.
- (d) The positive public relations exposure from implementing sustainable supply chain policies can generate numerous intangible benefits for companies. Sustainability is

synonymous with corporate social responsibility and being a good global citizen.

- (e) Suppliers and business customers are increasingly mandating the sustainable practices of their vendors.
- (f) The critical benchmark of sustainability is the eradication of waste in the supply chain.

Making a Supply Chain Sustainable

A sustainable supply chain is managed using four hierarchical strategies – legal, ethical, responsible, and sustainable. For example, a responsible supply chain must be legal and ethical, but not necessarily sustainable. The complexity of supply chains makes it difficult to determine whether it is meeting the social and environmental aspects of sustainability. Very little work has been done to address the performance of social or environmental issues. For example, none of the 2555 supply chain metrics that were reviewed explicitly addressed sustainability (Ahi and Searcy 2013). Another example is that only 5% of reviewed corporate responsibility reports of approximately 40,000 referred to ecological limits. There is a need for monitoring and compliance of sustainability targets for environmental and social measures, since companies are gradually being held responsible for harmful activities to the society or environment carried out by suppliers at all levels throughout their supply chain.

A sustainable supply chain is only as strong as its weakest link. Objective metrics and targets are already established for meeting some of the environmental goals, such as capping greenhouse gas emissions. It is encouraging that nearly 200 businesses committed to achieving this environmental goal. *Unilever*, a multinational company, has also established several science-based targets as a part of its Sustainable Living Plan, many of which will require their supply chain partners to meet the sustainability target. However, for social issues, measurement metrics are not very well defined. Sustainable development goals and *Oxfam*'s social foundations provide some guidance towards meeting the social aspect of sustainability in the supply chain.

Focusing on the Source to Create a "Sustainable Supply Chain"

Focusing on the source can help create a sustainable supply chain (Bove and Schwartz 2016). It was found that the supply chain of a consumer company accounts for greater social and environmental cost than its own operation. For example, 80% of greenhouse gas emissions and more than 90% of the impact on air, land, water, biodiversity, and geological resources are created by supply chain that can be reduced significantly by focusing on their supply chains.

Climate change has an adverse effect on the supply chain. For example, drought in Australia reduced a company, *Grain Crop*'s grain deliveries by 23%, leading to a 64% drop in 2014 profits. *Unilever* reported an estimated 3000 million pounds per year loss due to water scarcity and declining agricultural productivity leading to higher food costs. The deadly collapse of *Rana Plaza Factory* in Bangladesh resulted in two of the world's 100 most prominent apparel company to be dropped out of the list in 2 years after the incident.

The *Sustainability Consortium* (TSC), a non-profit organization dedicated to improving consumer products' sustainability, has reported the responses of 1700 companies on the sustainability of their supply chains. Only one-fifth of the respondents had a comprehensive view of their supply chain's sustainability performance. More than half of the respondents were unable to determine sustainability issues in their supply chain. The consumer companies are capable of making their supply chains more sustainable by identifying critical issues deep into the supply chain, linking the company's supply chain sustainability goals to the global sustainability agenda, and helping suppliers manage their impact. Based on scientific research and consultation with more than 100 stakeholder organizations, TSC has built a set of performance indicators and a reporting system that highlights sustainability hot spots for more than 110 consumer product categories, covering 80–90% of consumer products' impact.

Consumer companies and retailers can influence their suppliers to reduce sustainability impact due to their high purchasing power. Collaboration with suppliers has found to be responsible for carbon emission reduction of more than 3.5 million tons with suppliers saving an average of \$1.3 million per emissions reduction initiative. Companies are currently helping their suppliers design and implement sustainability programs that support their own goals. For example, in collaboration with the *Environmental Defense Fund*, *Campbell Soup* company offers farmers technologies, guidelines, and products to help them to optimize their fertilizer use and improve soil conservation. To monitor sustainability practices of supplier farmers, *Unilever* developed a digital software with the *University of Aberdeen* and share it free with suppliers with the aim of procuring 100% of its agricultural content from sustainable sources by 2020.

Providing incentives to suppliers has been adopted by many companies. For example, *Walmart* has pledged that 70% of its sales would come from suppliers that use the company's sustainability index that employ's TSC's supply-chain performance indicators and reporting system. *Walmart* tagged the companies with the highest sustainability index scores with "made by Sustainable Leaders," thus providing recognition for their good deed.

Four Strategies for Creating a More Sustainable Supply Chain

The social and environmental sustainability in the supply chain can be fostered by maintaining long-term sustainability goals, requiring the first-tier suppliers to set up their own long-term sustainability goals, by including suppliers from all levels in the overall sustainable strategy and most importantly, extending the company's sustainable program to their suppliers. To identify the effective strategies in fostering sustainability in supply chain, three notable multinational companies (MNCs) and their suppliers were investigated. Villena and Gioia (2020) have suggested four successful strategies; they are summarized below:

1. *Direct approach*: A firm can define and monitor social and environmental goals for its first-tier suppliers regarding second-tier suppliers. For example, to encourage diversity, an automotive company mandated that their first-tier supplier to allocate 7% of their procurement spending to minority suppliers, and monitored if it was met over time. These actions helped to spread the sustainability standards throughout the supply chain. Additionally, working together, the firm and their first-tier suppliers can build a map of connectedness and interdependency of suppliers, including lower-tier suppliers.
2. *Indirect approach*: The companies can provide training and incentives for their suppliers to implement sustainable practices. This was found to be very successful in making substantial changes in supplier's manufacturing practices and requiring their suppliers to adopt sustainability practices, thus cascading the practice of sustainability throughout the supply chain. The indirect approach is based on fostering peer learning and providing incentives such as long-term contracts, or preferred status as sustainability awards.
3. *Collective approach*: Industry competitors can collaborate to establish sustainability standards and tools and hold their suppliers responsible for adhering to those standards. Working together, business alliances can achieve a more efficient system for their suppliers. Companies can help suppliers become members of the industry association, thus making them responsible for complying with industry standards. Once becoming members of these industry associations, first-tier suppliers can influence second-tier suppliers to follow sustainability standards to stay competitive.
4. *Global approach*: Collaboration with international organizations such as the United Nations Global Compact, an international effort to promote corporate social responsibilities and NGOs that share the same goals, helps multinational companies.

Besides those strategies, a few more things can be done to develop sustainable supply chains. For

example, an inspection of all three components of 3P (profit, people, and planet) are required for all levels of suppliers before approving them, instead of addressing only one P (profit) related issues such as cost, quality, delivery, and technology which has been the general practice particularly for suppliers beyond the first-tier. Furthermore, proper training and incentives are needed for procurement officers at all levels of the supply chains, particularly at the first-tier suppliers, to mandate the social and environmental aspects of sustainability to the lower-tier suppliers. In addition, engaging the top executives of the first-tier suppliers are effective in developing sustainable supply chains at all levels. It is important to convey a consistent message of achieving all 3Ps – the economic, social, and environmental goals to the procurement officers, and all tiers' suppliers.

Summary and Conclusion

Highly functioning supply chains should focus on environmental and social factors, in addition to creating greater efficiencies (Brandenburg et al. 2014). Companies are increasingly focused on sustainable products and the extent to which the supply chains contribute to global sustainability challenges and how they contribute positively to their growth and long-term profitability.

Companies managing their supply chain impact are best positioned to gain a competitive advantage in the marketplace. More substantial social and environmental aspects of sustainability measures will influence company growth – poor performances will slow down growth. To achieve strong growth, companies can build partnerships with their suppliers to improve the social and environmental outcomes. By partnering closely with their suppliers, companies can lessen their environmental and social impact, and position themselves for greater success.

Sustainable Tourism

Cecilia Chirieleison¹ and Francesco Rizzi²

¹Department of Political Science, University of Perugia, Perugia, Italy

²Department of Economics, University of Perugia, Perugia, Italy

Synonyms

Eco-tourism; Ethical tourism; Green tourism

Definition

Sustainable tourism is any activity of persons traveling to and staying in places outside their usual environment that adheres to commonly accepted sustainability criteria.

Introduction

Tourism is one of the fastest growing industries in all continents. In 2005, tourism accounted for 10% of the world's economic activity and was already one of the main generators of employment.

According to the United Nations World Tourism Organization (UNWTO), tourism conventionally comprises the activities of people traveling to and staying in places outside their

usual environment for a limited time for leisure, business, and other purposes. In the tourism business, natural resources are thus intensively used and consumed to guarantee high standards of mobility, accommodation, and local consumption (Pan et al. 2018). As a consequence, tourism can have major impacts on the environment, ecosystems, and economy but, favoring their openness, also on societies and culture. The positive or negative nature of these impacts, and thus the distinction between sustainable and unsustainable tourism, depends on how it is managed. It is thus not surprising that in the last 30 years sustainable tourism has emerged as the dominant paradigm in tourism development (Ruhanen et al. 2015). In the definition of UNWTO, sustainable tourism is the form of tourism that “takes full account of its current and future economic, social and environmental impacts, addressing the needs of visitors, the industry, the environment and host communities.” This entails meeting the needs of present tourists and host regions while protecting and enhancing opportunities for the future, without altering cultural integrity, essential ecological processes, biological diversity, and life support systems. Notably, this long-term conservation perspective reflects symbiotic relationships between ecotourism and natural resource conservation (Boley and Green 2016) that stem from the needs of both tourists and host regions to increase the carrying capacity of the destination so as to limit the trade-off between its current and future attractiveness.

History

The increasing globalization of the economy and the availability of cheaper and faster transportation systems have boosted the tourism industry in recent decades. The sudden rise of mass tourism in the 1960s, coupled with a lack of regulation and awareness of its direct and indirect impacts, attracted wide criticism for stimulating unfair investments, which consequently paved the way to the introduction of the phenomenon of sustainable tourism.

As noted in the 2015 United Nations Educational, Scientific and Cultural Organization (UNESCO) report entitled “Sustainable Tourism Development in UNESCO,” international action in this area, however, did not really take off until the early 1990s, when tourism was officially recognized as an important issue in international environmental politics, both in relation to the Convention on Biological Diversity and to Agenda 21.

The evolution of the debate on sustainable tourism, and the increasingly complex and multifaceted nature of sustainable tourism in the last 30 years, is effectively represented in publications by the largest think-tank on the topic, the United Nations World Tourism Organization (UNWTO).

The first publication of UNWTO arrived in 1992, “An Integrated Approach to Resort Development”.

The topic of natural protected areas was introduced in 2002 with the publication “Sustainable Tourism in Protected Areas – Guidelines for Planning and Management” (Eagles et al. 2002). In the same year, UNWTO published “Voluntary Initiatives in Tourism Worldwide Inventory and Comparative Analysis of 104 Eco-labels, Awards and Self-Commitments.”

The topic of climate change entered the debate on sustainable tourism in 2003 in the publication “Climate Change and Tourism.”

In 2004, UNWTO published the first study on poverty alleviation entitled “Tourism and Poverty Alleviation Recommendations for Action”.

The relationship between tourism and cultural heritage was introduced in 2008 in the publication “Tourism Congestion Management at Natural and Cultural Sites.”

The impact of tourism on biodiversity was discussed in 2010 in the publication “Tourism and Biodiversity – Achieving Common Goals Towards Sustainability.”

In 2011, UNWTO focused attention on the business case for greener and sustainable tourism, highlighting the role of green investments as a means to create jobs and reduce poverty while also improving environmental outcomes in the “Tourism” chapter of the “Green Economy Report” (see ► [“Green Economy”](#)).

The same evolution, from theoretical and methodological approaches to empirically driven theory testing and building works, emerges also in the last 25 years of scientific production (Ruhanen et al. 2015), which demonstrates the maturation of the field towards a progressively more rigorous and detailed search – from a “looking back in order to progress” approach – of in-field evidence of the links between sustainable tourism management and performance improvement.

As a consequence of this increasing body of knowledge, sustainable tourism management is nowadays considered a key means to achieving sustainable development. It is explicitly mentioned in three of the 169 targets referred to in the 17 Sustainable Development Goals (SDGs) adopted by the UN General Assembly on 25 September 2015 through the Resolution “Transforming our world: the 2030 Agenda for Sustainable Development.” Nonetheless, there are many more targets that do not explicitly mention “tourism” but where tourism is/could be very relevant in their achievement.

General Principles and Metrics

Sustainable tourism encompasses all the activities that, in short, determine the contribution of tourism to the sustainable development of a destination. Its key principles can be delineated as follows:

- Ensuring an optimal use of environmental resources so as to maintain essential ecological processes and conserve natural heritage and biodiversity
- Respect and conserve the socio-cultural authenticity of host communities while contributing to inter-cultural understanding and tolerance
- Promote viable, long-term economic operations that are capable of providing socio-economic benefits to all stakeholders, including poverty alleviation, stable employment, social mobility, and social services to host communities

As reflected in the 2007 European Commission Communication “Agenda for a sustainable and competitive European tourism,” supporting universal access to tourism, preserving natural and cultural resources, diversifying tourism offerings at the transnational level, reducing the seasonality of demand, promoting the wellbeing of the local community, increasing the accountability of destinations, and reporting and promoting quality standards aimed at reducing information asymmetries among stakeholders are cross-cutting priorities of modern tourism policies.

A precondition for sustainable tourism is the informed participation of all relevant stakeholders, which is key to understanding the interests at stake and ensuring effective and constant monitoring of impacts, introducing appropriate preventive and/or corrective measures whenever necessary. Local communities are both crucial targets and drivers of sustainable tourism, as their community attachment and community involvement, mediated by perceived benefits, are critical factors that affect the level of support for sustainable tourism development (Lee 2013).

Of course, among the different stakeholders, sustainable tourism should also maintain a high level of tourist satisfaction and ensure motivating emotions (Malone et al. 2014) and meaningful experiences for tourists, raising their awareness about sustainability issues and promoting sustainable tourism practices amongst them, so as to reduce both intended and unintended (i.e., linked to the attitude–behavior gap) impacts (Juvan and Dolnicar 2014).

In doing that, it should be considered that the concept of responsible tourism from the consumer perspective is heterogeneous and evolving, which calls for adaptation of top-down planning and communication approaches towards more bottom-up alternatives (Caruana et al. 2014).

Sustainable tourism management requires assessing and monitoring the impacts of current and future tourism development. Thus, there is need for clear indicators, analysis of carrying capacity, limits of acceptable change, and related benchmarks.

Unfortunately, aside from the difficulties in ensuring wide generation and collection of quality

data (Law et al. 2017), in the tourism industry it is traditionally difficult to select indicators that can be monitored on an ongoing basis to establish trends over time, to establish baselines, benchmarks, and targets against which different regions can be compared, and to distinguish between indicators that summarize the broader economic, social, or environmental context and those indicators that relate directly to specific policies. These difficulties have led to a proliferation of purpose-specific metrics and relatively few orchestration initiatives, like the launch of the European Tourism Indicators System (ETIS).

Despite some attempts to achieve commensurability and reductionism (Andersson and Lundberg 2013), most of the indicators in use fit the needs of nonreductionist multicriteria evaluations that are not aimed at finding optimal solutions, but at outcomes that build greater consensus across the various stakeholders.

In this framework, to establish shared metrics of sustainability in tourism, UNWTO launched, with the support of the United Nations Statistics Division (UNSD), the initiative “Towards a Statistical Framework for Measuring the Sustainability of Tourism (MST).” The guiding principle that lay behind this initiative is that credibility, comparability, and coherence of various measurement and monitoring programs pertaining to sustainable tourism (e.g., the derivation of Sustainable Development Goals (SDG) indicators and those of UNWTO’s International Network of Sustainable Tourism Observatories (INSTO)) are necessary to adequately identify good practices to be supported and diffused.

Managing Sustainable Tourism

Achieving sustainable tourism requires determination, a long-term oriented motivation, and a holistic and integrated (i.e., systemic) approach to managing the overall lifecycle of the tourist experience, which consists in its preparation, the journey, the stay, the journey back home, and the activities after returning home. Sustainable tourism performance thus depends on the concerns and behaviors of a variety of actors throughout

the lifecycle of the tourist experience, from salespeople in travel agencies (Aliperti et al. 2018; Chen and Peng 2014) to waste management companies at the destination (Law et al. 2017) and to tourists and their bottom-up conceptualizations of the phenomenon (Caruana et al. 2014).
